KEY TO DATES AND PAGES.

THE following table, giving a key to the dates of issue and the page numbers of the BRITISH MEDICAL JOURNAL and SUPPLEMENT in the first volume for 1929, may prove convenient to readers in search of a reference.

Serial No.	Date of Issue.	Journal Pages.	Supplement Pages.
3548	Jan. 5th	1 – 52	1 – 8
3549	,, 12th	53 – 88	9 – 16
3550	,, 19th	89 – 138	17 – 20
3551	,, 26th	139 – 184	21 – 28
3552	Feb. 2nd	185 – 232	29 – 32
3553	,, 9th	233 – 280	33 – 36
3554	,, 16th	281 – 332	37 – 48
3555	,, 23rd	333 – 382	49 – 52
3556	March 2nd	383 – 430	53 – 56
3557	,, 9th	431 – 486	57 – 60
3558	,, 16th	487 – 534	61 – 68
3559	,, 23rd	535 – 584	69 – 72
3560	,, 30th	585 – 628	73 – 76
3561	April 6th	629 – 670	77 – 84
3562	,, 13th	671 – 714	85 – 96
3563	,, 20th	715 – 752	97 – 152
3564	,, *27th*	*753 – 796*	*153 – 176*
3565	May 4th	797 – 838	177 – 184
3566	,, 11th	839 – 890	185 – 192
3567	,, 18th	891 – 938	193 – 200
3568	,, 25th	939 – 980	201 – 204
3569	June 1st	981 – 1024	205 – 212
3570	,, 8th	1025 – 1066	213 – 228
3571	,, 15th	1067 – 1104	229 – 236
3572	,, 22nd	1105 – 1146	237 – 248
3573	,, 29th	1147 – 1190	249 – 284

INDEX TO VOLUME I FOR 1929.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma, Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar; Light, Roentgen, Radium, X Rays; Status Lymphaticus and Thymus; Eye, Ophthalmia, and Vision Bicycle and Cycle; Motor and Automobile; Association, Institution, and Society, etc. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Correspondence," "Leading Articles," "The Week," "Reviews," etc. Original Articles are indicated by the letter (O).

A.

ABBOTT, Rev. J. E.: Notes on leprosy, 866
Abdomen, acute, prevention and early diagnosis of (Zachary Cope), 6 (O)—(E. G. Slesinger), 998
Abdominal aneurysm. *See* Aneurysm
Abdominal operations, use of heroin after: a warning (A. E. Mortimer Woolf), 499 (O)—(Donald Hall), 728—Correspondence on, 975
Abdominal swab stand, 255
Abdominal torsion of omentum. *See* Omentum
ABEL, R. Lawrence:—*Oesophageal Obstruction: Its Pathology, Diagnosis, and Treatment*, rev., 999
Aberdeen. *See* Scotland
ABERNETHY, D. A.: Torsion and strangulation of an hydatid of Morgagni, 144 (O), 320
Ability, estimation of, 515
Abnormalities, associated, congenital, 1060
Abortifacients, advertisements of, 358
Abortion, criminal, and the sale of abortifacient drugs (F. J. McCann), 202—Discussion, 203
Abortion, induction of, medical indications for (Eardley Holland), 600—Discussion, 600
Abortion, twin, from a uterus didelphys (R. J. Bannister), 16
ABRAHAMSON, L.: Digitalis in the treatment of auricular flutter, 853
Abscess, cerebral, following acute tonsillitis (E. Gerard Housden), 1158 (O)
Abscess, peritonitic, case of physopyometra with (Francis J. Hector), 1158
Abscess, peritonsillar, lancet for, 405
Abscess, temporo-sphenoidal, chronic (R. Vaughan Thomas), 902
Ar[illegible] the
Ar[illegible] tte-Guérin, 613, 1014—Prince of Monaco prize awarded, 736—New members, 1015
Academy, Royal (1929), 857
Academy, Royal, of Medicine of Belgium: election of officers, 231

ACADEMY, ROYAL, OF MEDICINE IN IRELAND:
Section of Anatomy and Physiology: Lumbar sympathectomy, 686—Urea equilibrium in the kidney, 687
Section of Medicine.—Differential diagnosis of splenomegaly, 249—Protein shock therapy, 451—Congenital pyloric stenosis, 452—Digitalis in the treatment of auricular flutter, 853—Pemphigus foliaceus, 854—Value of splenectomy in Banti's disease, 854
Section of Obstetrics.—Chronic metritis, 555—Sequels of radium treatment, 555—Anaesthesia in labour, 556

EPITOME

OF

Current Medical Literature.

JANUARY TO JUNE, 1929.

F. W. W. GRIFFIN, M.D.,
SUB-EDITOR.

London:
PRINTED AND PUBLISHED AT THE OFFICE OF THE BRITISH MEDICAL ASSOCIATION,
TAVISTOCK SQUARE, LONDON, W.C.1.

INDEX TO THE EPITOME FOR VOLUME I, 1929.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma; Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar; Eye, Ophthalmia, and Vision, etc.

The Figures in this Index refer to the Number of the Paragraph, NOT the Page.

A.

WITH SUPPLEMENT.

No. 3548. SATURDAY, JANUARY 5, 1929. Price 1/3

DEPENDABLE GLAND PRODUCTS

Our organotherapeutic products are made in our own laboratories from the fresh glands of healthy animals under the supervision of competent chemists.

CORPUS LUTEUM	PANCREAS
LIVER	PARATHYROID
MAMMARY	PITUITARY
ORCHIC	SUPRARENAL
OVARIAN	THYMUS
PINEAL	THYROID

Every product is tested whenever practicable for its activity and stability by chemical or biological assay, and a definite standard is maintained.

Our complete list of single gland substances and combined gland products will be sent to members of the medical profession on request.

G. W. CARNRICK CO.,

Dependable Gland Products.

London Agents: BROOKS & WARBURTON, Ltd., 40-42, Lexington Street, W.1.

Specify—CARNRICK. (TRADE MARK.)

C. F. THACKRAY ▾ PARK STREET, LEEDS ▾ 119 HIGH HOLBORN, LONDON, W.C.I

The Therapeutic value of BRANDY—

its lifting and sustaining powers—as compared with other spirits depends on the presence or absence of the higher Alcohols or Ethers. These in turn depend on Grape, Soil, Stills employed, Climate, Storage, Selection and Experience.

It is quite easy to make a spirit from grape wine—It is neither easy nor cheap to make a Brandy containing the qualities you want.

Cognac Brandy alone provides them.

Take no risks; ensure the results you expect

Prescribe Brandy distilled in Pot Stills from Wines grown in the best Cognac districts; Matured in warehouses which have been filled with Cognac Brandy for centuries; Made by Men with the inherited Experience of Seven Generations.

In short—Prescribe MARTELL'S BRANDY

and know that you are doing the best possible for your patients.

British Medical Journal.

The Issue of the BRITISH MEDICAL JOURNAL is this week 39,000 copies.

Just Ready!

Wayne Babcock's Surgery

DR. BABCOCK based his book absolutely on surgical anatomy and physiology, because he believes that the practice of surgery is nothing more nor less than applied anatomy, applied physiology, applied physics, applied chemistry, applied bacteriology and pathology.

The plan of the book is this: There is a section on General Surgery, paralleling a course in general medicine and general pathology. There is a section on Technique, to serve as a guide in the surgical laboratory, in the clinic, and in the operating room. There is a section on Special or Regional Surgery, presenting the work of the senior and hospital year and of post-graduate practice.

Surgical Diagnosis is given the full consideration its importance merits. Indeed, the entire book is extremely well-balanced—every subject is given its proper and proportionate discussion.

The 1,050 illustrations are nearly all original and reflect the high standard of the Max Brödel school. Through these illustrations diagnostic errors and common technical mistakes are visualized; the right way is contrasted with the wrong way of doing things; and in many cases the step-by-step illustrations show the operative technique almost independently of the text.

The book not only tells—and shows—what to do, but also how to do it; indicates the limitations of each procedure; avoids the speculative and theoretical; and strongly stresses the practical. It is a dogmatic interpretation of general surgery based on thirty years of teaching and practice in the laboratory, the clinic, and the operating room.

Undoubtedly, Dr. Wayne Babcock's "Surgery" will spring into immediate favour with teachers, students, surgeons, and general practitioners, because it is refreshingly new in its text, in its illustrations, and in its freely-flowing style; because it is the work of an experienced teacher and surgeon; because it is comprehensive yet not unduly large; because it is based on the fundamentals of good surgery—anatomy and physiology.

Octavo of 1,367, with 1,050 illustrations, 9 in colours. By W. WAYNE BABCOCK, M.D., Professor of Surgery, Temple University, Philadelphia. Cloth, 45s. net.

Boyd's Surgical Pathology.

By WILLIAM BOYD, M.D., M.R.C.P.Ed., F.R.S.C., Professor of Pathology, University of Manitoba. Octavo of 837 pages, with 349 illustrations, and 13 colour plates. Cloth, 45s. net.

"The author's easy style, his philosophic, controlled breadth of view, his wide knowledge of his subject from both the clinical and laboratory sides, are all factors combining to make the appearance of this volume the event of the surgical literary year."—IRISH JOURNAL OF MEDICAL SCIENCE.

MacCallum's Text-book of Pathology.

By W. G. MACCALLUM, Professor of Pathology, Johns Hopkins University, Baltimore. Third Edition. Octavo of 1,162 pages, with 575 original illustrations, many in colours. Cloth, 45s. net.

"One of the most trustworthy expositions of the subject. . . . No student possessing such a volume will wish to be done with pathology when he has passed his examination."—EDINBURGH MEDICAL JOURNAL.

Arey's Developmental Anatomy.

By LESLIE BRAINERD AREY, Professor of Anatomy at the Northwestern University Medical School, Chicago. Octavo of 433 pages, with 419 illustrations, many in colours. Cloth, 27s. 6d. net.

"May be highly recommended, and is likely to be used very widely."—BRITISH MEDICAL JOURNAL.

Ford's Text-book of Bacteriology.

By WILLIAM W. FORD, M.D., Professor of Bacteriology, School of Hygiene and Public Health, Johns Hopkins University. Octavo of 1,069 pages, illustrated. Cloth, 37s. 6d. net.

"This is one of the most complete single-volume works on bacteriology. It is more than a text-book, as it is described, and constitutes a valuable work of reference with a wealth of detail particularly in systematic bacteriology. . . . The book can be strongly recommended."—EDINBURGH MEDICAL JOURNAL.

Cecil's Text-book of Medicine.

Edited by RUSSELL L. CECIL, A.B., M.D., Assistant Professor of Clinical Medicine, Cornell University. Octavo of 1,500 pages. Cloth, 40s. net.

"This book maintains a very high level throughout its pages. . . . Great care has been taken with the dovetailing together of the various contributions into a compact whole, and the book is a worthy production of the modern American school of medicine."—LANCET.

Howell's Text-book of Physiology.

By WILLIAM H. HOWELL, M.D., Ph.D., Professor of Physiology, Johns Hopkins University, Baltimore. Tenth Edition. 8vo of 1,081 pages. Cloth, 30s. net.

"One of the best, most readable, suggestive, and withal critical of the modern text-books on this subject. Is sound, accurate, philosophical, and thoroughly up to date."—LANCET.

W. B. SAUNDERS COMPANY LTD. 9, Henrietta Street LONDON, W.C.2

DISEASES OF THE HEART

THEIR DIAGNOSIS, PROGNOSIS AND TREATMENT BY MODERN METHODS.

With chapters on the Ink Polygraph, Clinical Electro-Cardiography, X-Ray Examination, and Anæsthesia in relation to Cardio-Vascular Affections.

By FREDERICK W. PRICE, M.D., F.R.S.(Edin.).

Physician to the National Hospital for Diseases of the Heart; Consulting Physician to the Royal Northern Hospital, London.
Demy 8vo. Pp. 534. With 249 text figures, including 32 sphygmograms, 92 polygraphic tracings, and 87 electro-cardiograms.

NEW SECOND EDITION, 21s. net.

"Dr. Price has accomplished his avowed object of presenting concisely information of service in the diagnosis, prognosis, and treatment of diseases of the heart by modern methods."—BRITISH MEDICAL JOURNAL.

"The most valuable and comprehensive guide to the study of Cardiology with which we are acquainted.—NEW YORK MEDICAL JOURNAL AND RECORD.

"We think that most of our readers engaged in general practice will find this work extremely useful."—THE JOURNAL OF CLINICAL RESEARCH.

"In our opinion the book is indisputably the most authoritative contribution to Cardiology of our time."—FRANCO-BRITISH MEDICAL REVIEW.

"A book which we believe is destined to remain the standard work on Cardiology for many years to come"—AMERICAN MEDICINE.

"The second edition of this popular work on heart disease bears evidence of thorough revision, while the essentially clinical standpoint of the writer is maintained."—EDINBURGH MEDICAL JOURNAL.

"It may be said at once that the book adequately fulfils the purposes it has in view, and is a perfectly sound, lucid, and reliable guide."—NEWCASTLE MEDICAL JOURNAL.

"Well-written, concise, and complete, containing a wealth of practical information. Obviously based upon the author's own experience and investigative work."—SURGERY, GYNECOLOGY AND OBSTETRICS (Official Journal of the American College of Surgeons).

"Dr. Price is to be congratulated again on the reappearance in its second edition of his distinguished contribution to the increasingly important subject of Cardiology."—THE CANADIAN JOURNAL OF MEDICINE AND SURGERY.

OXFORD UNIVERSITY PRESS, Amen House, Warwick Square, London, E.C.4.

Third Edition.

A TEXTBOOK OF
EXPERIMENTAL PSYCHOLOGY

By CHARLES S. MYERS, M.A., M.D., Sc.D., F.R.S., and F. C. BARTLETT, M.A.

Demy 8vo. In 2 parts, complete. 16s. net.

The two parts are also sold separately PART I. Textbook, 10s 6d net; PART II. Laboratory Exercises, 7s net.

"No worker in psychology can afford to dispense with this excellent textbook, while the physician opening it at random will find material to engross him on almost every page."—*Lancet*, on the Second Ed.

CAMBRIDGE UNIVERSITY PRESS, Fetter Lane, London, E.C.4.

Intestinal Disinfection

RHEUMATOID ARTHRITIS

UNDER this name, several conditions which are ætiologically distinct are doubtless grouped together, and we are still far from a solution of the cause of the disease.

It is obviously impossible to restore in any marked degree mobility to the joints of the hopelessly crippled, but in the early stages much may be done to retard or stop the progress of the disease.

An eminent surgeon has directed attention to the rôle of chronic intestinal stasis and alimentary toxæmia in the production of the disease, and has emphasised the need for intestinal disinfection.

For this purpose nothing surpasses the use of Kerol Capsules. Kerol is a potent and non-toxic germicide which is unabsorbed from the intestine, so that the whole of its germicidal power is exerted upon the contents of the bowel.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

Most nourishing Bread

After all the discussions as to the relative values of white, wholemeal, and various brown breads, it is satisfactory to have conclusive evidence at last.

Following many experiments by various research workers it is shown that no bread contains so large a percentage of Vitamin B as HOVIS, or is such an active agent for healthy growth when forming the basis of the diet.

As is now well known, even a partial deficiency in Vitamin B in the diet, if lasting for any length of time, impairs health, and, with children, prevents perfect development.

HOVIS, even in small quantities, provides sufficient vitamin in a digestive form as no other bread does, and it is liked by all.

Richest in Vitamin B

HOVIS Bread consists of White Flour with the wheat germ incorporated. It is this which gives it its special value, since the germ is the part richest in the Vitamin.

The "brownness" of bread is not a measure of its vitamin content. HOVIS does not contain bran, and is easily digestible.

Note the following figures showing the Vitamin B content of milling products and yeast in 100 g. dried bread:

White Bread	200
Wholemeal Bread	1,450
HOVIS Bread	2,600

The evidence is conclusive. For providing the maximum of nourishment economically no bread equals HOVIS.

HOVIS LTD. LONDON & MACCLESFIELD

For patients who lead sedentary lives

The addition of a little Marmite to the ordinary diet proves helpful in counteracting that tendency to defective elimination and digestive disturbance which are so common among persons engaged in sedentary occupations.

As Marmite is a Yeast Extract, it can be relied upon to make good the deficiency of Vitamin B, which is so frequently associated with the disabilities in question.

MARMITE

Marmite is very palatable and is easily administered in sandwiches and as a consommé made with hot water. Or it maybe added (in the quantityrecommended in the printed instructions) to stews, gravies, etc.

Medical Practitioners are invited to write for a sample of Marmite, together with full evidence of its usefulness. The Marmite Food Extract Co., Ltd., 59, Eastcheap, London, E.C.3.

Bemax strengthens and invigorates the muscular tissues generally. Moreover, it is very pleasant to take. It is in every way a very good food. L.R.C.P., M.R.C.S.

The original of this report may be seen by any registered medical practitioner at our office. Information about our experiments and the constant research work our laboratories are doing in connection with Bemax, will be gladly forwarded on application to the address given below.

WRIGHT'S LYSOL

BRITISH MADE :: :: BRITISH OWNED

The quality of WRIGHT'S LYSOL *has never been questioned*

It is safe to prescribe Wright's Lysol — safe because you know that your patients will then get a pure and highly refined Lysol, controlled by the Rideal-Walker test. Wright's contains no free alkali — does not sting or irritate — gives certain results. It is widely used by the profession; Hospitals and Nursing Homes prefer it.

Tell your patients always to say "Lysol." "Wright's" before

British owned and British made by the makers of the world famed Wright's Coal Tar Soap.

A handy graduated measure is provided with every bottle.

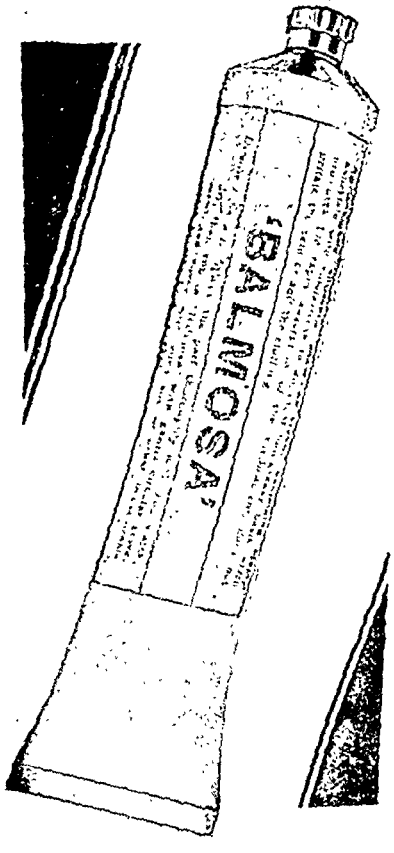
A HIGHLY PENETRATIVE CREAM FOR LOCAL TREATMENT OF RHEUMATISM



Local pain and swelling due to acute rheumatism or joint diseases have proved unusually susceptible to the salicylate present in "Balmosa". The exceptional penetrative properties of the non-greasy base of this cream ensure almost instantaneous action upon the affected part. Pain is speedily relieved; swelling is materially, if not wholly, reduced.

Manufacturers of Roboleine the Reconstructive Food

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.

It cannot harm the most delicate constitution and is at all times a safe and effective aperient.

Pneumococcus Antibody Solution

because

It is a specific treatment for the lobar pneumonias caused by Types I, II, or III *pneumococcus*.

It has been subjected to a thorough clinical trial over a period of six years in both hospital and private practice. It has been used in about 2,000 patients in private practice. Published reports cover nearly 1,000 cases.

When used early (on or before the third day), a definite shortening in the duration of the disease and a reduction of 50 per cent. in the *mortality rate has been reported.*

Serum sickness and anaphylaxis have not been observed in any instance.

It contains the pneumococcus protective antibody in the purest form generally available.

Typing, as a preliminary procedure, is unnecessary and causes delay. Experience has shown that the most benefit is derived from very early treatment.

The dangerous bacteriemia accompanying many cases of pneumonia can often be controlled by this agent, especially in Type I cases.

Intravenous administration is the preferred method, because the antibodies are thus made immediately available in the blood stream.

Thermal reactions, while they sometimes occur, are controllable by usual methods.

INSULIN 'A.B.'

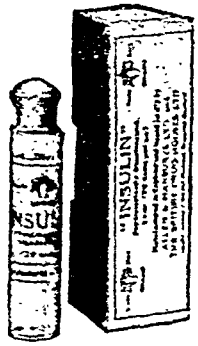
TRADE A B MARK **Brand**

"A.B." Insulin was the first British Insulin available for use by the Medical Profession and after almost five years retains its reputation as the Insulin which can be relied on to give consistently satisfactory results. The supremacy of "A.B." Insulin is due entirely to the stringently high standards of purity, therapeutic efficiency and stability self-imposed by its manufacturers.

"A.B." Insulin connotes:

Uniformity of unitage.
Full potency and stability in all climates.
Purity and complete sterility.
Absence of reaction-producing proteins with consequent noteworthy freedom from unpleasant by-effects.

The activity of "A.B." Insulin is guaranteed by the most complete physiological tests and standardisation on the basis of the accepted unit. Before issue, each batch is passed under the authority of the Medical Research Council.



Supplied in two strengths:

20 units per c.c.

Packed in bottles containing:

5 c.c. (100 units or 10 doses) 2/8 each

FELLOWS MEDICAL MANUFACTURING CO., Inc.
26 Christopher Street, New York, U. S. A.

For Ill Conditions of the Gastric Tract

"Alocol" is the practitioner's safeguard when alkaline medication is indicated. Its clearly defined antacid properties exceed those of bicarbonate of soda, magnesia, and subnitrate of bismuth; furthermore, "Alocol" eliminates all the unpleasant drawbacks which are particularly feared with the usual alkalis and oxides.

When "Alocol" reaches the stomach adsorption takes place; a colloidal jelly is formed, which, adhering to the walls of the stomach, diminishes their sensibility. The excess of hydrochloric acid is absorbed, but the acid reaction necessary for peptic digestion remains normal.

The advantages of "Alocol" are therefore manifest. It neither hinders proteolysis nor causes destruction of any food element or factor. Prolonged exhibition interferes in no way with the normal putrefactive function of the gastric juices, or with the regular processes

"Alocol" is regarded as a specific in the treatment of hyperchlorhydria, whilst for all forms of fermentative dyspepsias, with gastro-intestinal flatulence, acid eructations, and other symptoms common to gastric disease, its influence is beneficial to the highest degree.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

The confidence of the MEDICAL PROFESSION.

Benger's Food has gained its unique position, not by extravagant or sensational advertising but by the constant recommendation of medical men and women. To-day it is universally used not only at home but throughout the world. Few foods have so enjoyed the approbation of the Medical Profession for over 40 years.

Benger's Food differs from all other foods in that it is especially prepared to adjust fresh cows' milk or cows' milk and water so as to suit the condition of any patient. While it is largely used as a routine treatment in all cases of disordered digestion the following comments, which have been recently made by Doctors, indicate some specific uses to which Benger's Food has been put.

DYSPEPSIA.

"routine food in all cases of dyspepsia and disordered digestion."

"used for invalids and all gastric cases."

INFLUENZA.

"very largely used for Influenza in all its forms."

CANCER.

"invaluable for cancer of the throat."

"cancer of the stomach—doing well on Benger's Food."

THE AGED.

"very beneficial for man of greatly advanced years."

"invariably used for invalids and aged persons."

A Physician's Sample will be sent post free to any member of the Medical Profession making application to the Proprietors—

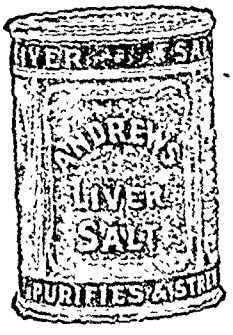
A useful Saline Aperient

Andrews Liver Salt is an ideal Saline aperient of pleasant taste, readily taken and well tolerated by the most delicate adult or child. It ensures an easy and complete evacuation without griping or tenesmus; it is not contra-indicated in the majority of diseases where constipation arises.

It acts by stimulating the intestinal glands, thus increasing the fluid content of the bowel, producing gentle peristaltic contractions and a natural and efficient clearance of the colon and rectum without any unpleasant after effects.

In cases of fever, its brisk effervescing solution in water makes a refreshing and invigorating drink, relieving thirst, diluting the toxins and relieving the strain upon the kidneys.

It may be used as a hydragogue purgative in the treatment of oedema, ascites, pleuritic effusions and nephritis, and with safety even in failing cardiac conditions.



Andrews Liver Salt is prepared with the greatest possible care to secure uniformity of composition, under hygienic conditions and from the purest ingredients obtainable, each batch being tested by our Staff Analyst.

An 8-oz. tin will be sent free on request.

Andrews Liver Salt

SCOTT & TURNER LIMITED, Works and Laboratories at Newcastle-on-Tyne

RADIO-MALT

The original vitamin tonic

For the past two years Radio-Malt has proved itself to be of great value in all cases where there is a definite vitamin deficiency, and since it was made available to members of the medical profession two years ago physicians throughout the English-speaking world have been obtaining some remarkable results from its use.

Radio-Malt contains all three Vitamins A, B and D in scientifically-harmonised quantities, accurately-standardised in the B.D.H. laboratories by physiological tests on animals.

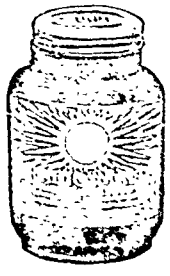
The Vitamin A is extracted from mammalian livers by a process discovered and developed in the B.D.H. laboratories. It is on account of its power to give resistance to infection that Vitamin A is important during the winter season.

The Vitamin B is extracted in the B.D.H. laboratories from seed germ.

The Vitamin D—the antirachitic vitamin—is manufactured in the B.D.H. works by the irradiation of ergosterol.

The B.D.H. irradiation process has been perfected with much experimentation, with the result that the irradiation is carried out in such a way that a product (Radiostol) is always obtained which is of optimum Vitamin D activity.

The importance of correct irradiation cannot be over-estimated; under-irradiation yields a comparatively inactive product, whilst over-irradiation converts the Vitamin D already formed into an inactive product which is also toxic. Radiostol is neither under-irradiated nor over-irradiated; it is the intermediate, correctly-irradiated, pure product. It is present in Radio-Malt in the proportion of 1,000 antirachitic units per ounce.



Samples on request

Radio-Malt is accurately-standardised and, therefore, more reliable than cod-liver oil and malt; also it is more concentrated and more intensive in its effects.

RADIOSTOL and RADIO-MALT are available from leading pharmacists

FOR TOXÆMIAS OF INTESTINAL ORIGIN

Kaylene-ol

is an effective detoxicating agent and one of the simplest to employ. It does not merely lubricate the bowel, but also fixes the toxins in the Stool.

It actively prevents the absorption of toxins and completely puts an end to the fouling of the lymphatics and the blood.

KAYLENE-OL c̄ PHENOLPHTHALEIN

CONSTIPATION OF PREGNANCY.

"The preparations of KAYLENE, and especially KAYLENE-OL c̄ Phenolphthalein, are proving useful in pregnancy. The latter gives generally two very easy actions a day, has a helpful effect on the nausea, and lessens the chances of intestinal toxæmias of pregnancy. Further, it need not be taken in increasing doses, but may rather be employed in gradually reduced quantities. As constipation is almost universal in pregnancy, the benefit from such preparations will be apparent."

Samples and particulars of Kaylene and its preparations forwarded on request.

Norwegian Cod Liver Oil for all Children

The pale, thin and weedy children of whom one sees far too many in the large towns, frequently fall an easy prey to infectious diseases such as bronchitis, broncho-pneumonia, diarrhoea, etc.

In such cases Cod Liver Oil frequently has an excellent effect, not because of any direct antiseptic influence, but because it increases the powers of the body to resist and fight disease.

At many Welfare Centres, Schools and other Clinics, all babies are given systematically a teaspoonful of Cod Liver Oil a day.

If you are interested, please send a post-card to the address below for a copy of a pamphlet «On the Effects and Medicinal Use of Cod Liver Oil». It will be sent gratis and post free.

National Committee for Promoting the Consumption of Norwegian Cod Liver Oil, Bergen, Norway.

FABRITIUS, OSLO.

Alternative Methods in the

TREATMENT OF BOILS CARBUNCLES & FURUNCULOSIS

Antivirus

The latest method, which has proved so useful with patients who object to injections, consists of local treatment with Staphylococcus Antivirus. Reports from hospitals and Skin Specialists state that this Antivirus is as efficient or more efficient than subcutaneous inoculations with Vaccine.

Detoxicated Vaccine

Practitioners who prefer the more orthodox forms of treatment are recommended to use Detoxicated Staphylococcal Vaccine; its special feature is the production of great immunity with little or no reaction. This is achieved by removing all the toxic elements of the germ during the preparation of the Vaccine. Doses up to 50,000 millions are given without malaise.

Ordinary Vaccine

To meet the requirements of those who consider that a slight reaction has definite therapeutic value Ordinary Staphylococcal Vaccine is available. It has proved generally successful and is very inexpensive.

'PANOPEPTON'

LEAN BEEF—the entire group of nitrogenous substances, those natively soluble and those rendered soluble by physiological hydrolysis; amino-acids, and polypeptids with the natural savoury extractives and minerals:

ENTIRE WHEAT GRAIN—the peculiar complex of nitrogenous substances, those naturally soluble and those rendered soluble by physiological hydrolysis, amino-acids, and polypetids, the farinaceous substance converted into dextrin and maltose, and with the associated savoury constituents and minerals.

Of the beef nothing is excluded but the indigestible connective tissue and lipoid. Of the wheat nothing is excluded but the insoluble inert cellulose and silica of the shell of the grain.

In the preparation of 'Panopepton' the raw beef is submitted to the action of gastric juice extract at normal temperature and acidity to a complete conversion of the proteins; the clarified solution concentrated in vacuo.

The hard wheat grain, well-cooked like a cereal, is subjected to both proteolytic and amylolytic digestion by a freshly prepared pancreas gland extract at normal media and temperature, until free from coagulable protein, and free from starch.

The soluble concentrates of the beef and wheat are combined on the basis of assay. The finished product contains 24% of total dry solids:

Protein	6.50	
Carbohydrates	16.50	
Ash	1.	—24.00

'Panopepton' is of a uniform standardized composition; it is highly agreeable; requires no preparation. It is a potent restorative and emergency food in serious straits; a fortunate recourse for the invalid.

SUPPLIED IN 12-oz. BOTTLES.

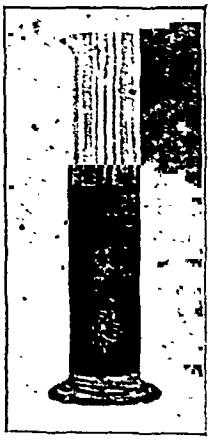
'Allenburys' The A DIET

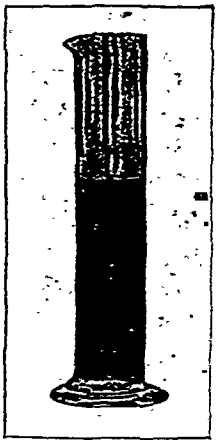
A Stimulating and Sustaining Food Beverage



A Showing the heavy curd formed by the action of gastric juice on ordinary cow's milk

A solution to the problem of feeding in many acute and chronic affections is found in the use of the 'Allenburys' Diet, which presents distinct advantages over cow's milk both with regard to food value and digestibility. The 'Allenburys' Diet is a palatable and highly nutritive food beverage prepared from pure fresh full-cream milk and whole wheat, and is particularly easy of assimilation. It replaces with advantage milk and the milk dishes commonly employed in sickness and convalescence and can often be taken and retained where other foods are rejected. As a stimulating and sustaining beverage for people of all ages, it is infinitely superior to tea, coffee, etc. It can be made in a minute simply by adding either boiling water or milk.

In tins at 2/1, 4/- and 7/6.



B Showing the finely flocculent curd formed by the action of gastric juice on the 'Allenburys' Diet.

Descriptive Literature and free clinical sample will be gladly sent on request.

REMAINS OF AN ANCIENT KELTIC IRON-FURNACE AND A PAIR OF BLACKSMITH'S PINCERS.—In many of the localities inhabited by the ancient Kelts are to be found the remains of furnaces and other relics of the iron-working industry, of which these people were famous pioneers. Julius Cæsar was greatly impressed by the skill of the Gaulish blacksmiths, and records his admiration for the iron anchor-chains they made. Plutarch records that a certain military officer was obliged to have metal helmets made for his men to resist the Keltic swords, "which were the greatest strength of these barbarians." Machines and agricultural appliances, made of iron or requiring iron in their composition, were well-known as their handiwork. Pliny states that they possessed mowing machines, a borer with a spiral, and four-wheeled chariots. An immense variety of tools and utensils forged by them characterise the later Iron Age. The Keltic furnace for the extraction of iron from its ores was a simple cavity, generally in the side of a hill, its walls being constructed of the local stone. It was filled with ore in horizontal layers alternating with layers of charcoal. An opening at the base permitted of ventilation by a natural draught and perhaps by means of a primitive bellows, while through it, too, the iron-worker withdrew the lumps of metal. Present-day experiments have shown that these ancient furnaces, worked with simple bellows, would yield, in 48 hours, 25 lb. of iron so pure that it could at once be forged into lance-heads.

DELIVERED TO THE LEEDS UNIVERSITY MEDICAL SOCIETY, NOVEMBER 20TH, 1928,

BY

SIR JOHN BLAND-SUTTON, BT., LL.D., F.R.C.S.,
CONSULTING SURGEON TO THE MIDDLESEX HOSPITAL.

Women shall bring forth monsters.—II Esdras v, 8.

CONJOINED twins, or monsters, which is the vulgar name for these unfortunate human beings, have interested the world for centuries. Anatomists one hundred years ago called them "freaks." In museums of pathology many double foetuses are preserved and shown to visitors as curiosities. This is pardonable because it was impossible to give an explanation of such conditions on account of the ignorance of the prime factors concerned in animal reproduction.

Conjoined twins interest embryologists, doctors, midwives, surgeons, and psychologists.

Embryologists are mainly concerned with their origin. One ovum, as a rule, gives rise to one embryo; not infrequently an ovum may be the source of two embryos; each may be a separate individual, be born, mature, manifest average mental capacity, physical power, and reproductive ability. Mammals are known in which a single ovum may give rise to several embryos. Thus in the nine-banded armadillo, *Tatusia novemcincta*, from one ovum four embryos normally arise (Fig. 1). They are of the same sex. This is called polyembryony.

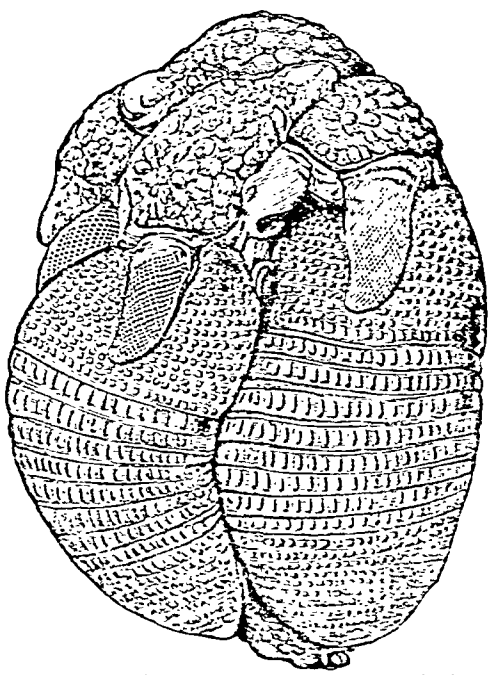

FIG. 1.—Quadruplets of the Nine-banded Armadillo, developed from a single ovum.

Embryologists are occupied with the experimental production of double creatures such as starfishes, newts, salamanders, and the like. The eggs of such aquatic forms are large enough to permit of delicate manipulation, and some experimenters are so clever that they can divide the developing ovum, either with an extremely fine needle or a fine sterilized hair, without arresting the growth of the ovum, and then observe the fragments develop into complete individuals, or become monstrous forms. In one lucky instance an embryologist (Clarke), studying the development of the American salamander, noticed something unusual with the anterior extremity of the medullary fold; he set the egg aside and had the satisfaction of watching the development of a two-headed salamander.

Conjoined twins are common among salmon-fry in hatcheries; they have also been observed in many classes of vertebrate animals—fishes, reptiles, birds, and mammals. Examples are preserved in all well-stocked anatomical museums throughout the world.

Doctors and midwives are concerned in the delivery of twins—especially the birth of monsters, but mainly in regard to the safety of the mother. Judging from the large number of monstrous twins preserved in museums, conjoined twins rarely survive their birth. In some cases Caesarean section is required. In many instances the mothers are multiparous; in some of the best known the reports run: "the twins were born without difficulty." The mother of the Siamese twins Chang—Eng (Fig. 2) stated that the head of one twin was between the legs of the other, and they were born easily. When Laloo (Fig. 3) was born the arms of the parasite were around the neck of the autosite.

In Eastern countries conjoined twins of any kind are regarded as portents. When Chang—Eng were born the King of Siam, conceiving them to be monsters, imagined they portended evil and designed them to be put to death (*Phil. Trans.*, 1830, 177).

Surgeons critically study conjoined twins because they have to exercise their wits as to the possibility of separating them successfully. This matter has received attention in individual cases from surgeons of the highest reputation and skill.

Although the object foremost in my mind in this lecture is to discuss the psychology of these persons who, when inseparable surgically, are condemned to a life of bondage, it will be necessary to describe some examples illustrating the various forms such twins assume.

CONJOINED TWINS.

The best known example of this variety is the Siamese twins Chang—Eng. They were discovered by Captain R. Hunter in 1829: the twins were fishing in the Siam River; they were naked above the waist, and he imagined them to be some rare animal. Hunter ascertained from their mother that they were born without difficulty; he saw them when they were 18 years of age. Sir William Fergusson examined them (1829) in regard to the question of separation, and did not favour operative intervention. The twins were exhibited in New York as Chang and Eng Bunker. They were skilful at battledore and shuttlecock, became affluent, and married two sisters—daughters of a Wesleyan minister. Chang had ten children and Eng twelve. The twins were shown in England in 1869, and

were seen again by Fergusson, and he decided against separation. The desire for separation had increased "as each family wanted to have a father all to itself."

Chang—Eng died in 1874 within two hours of each other, aged 63.

PARASITIC TWINS.

In the case of duplex twins, when one of them is incomplete, the well-developed twin is known as the *autosite*; the imperfectly developed twin is called the parasite. This variety of conjoined twins is called parasitic twins. The parasite assumes various forms; when the head is lacking the parasite is said to be acephalous. In such a condition the anatomical relationship has been graphically described "as if the parasitic twin had plunged its head into the autosite's breast" (Fig. 3).

A good example is Laloo, an intelligent Hindu, who was exhibited in London, aged 17 years. I had an opportunity of thoroughly examining Laloo with the late S. G. Shattock, and drawing up a joint report for the Pathological Society of London. I have seen Laloo many times since. He was shown as "a boy and girl joined together alive." There was no doubt about the sex. They were two males, each with well-developed external genital organs. In conjoined twins the sex is identical. I know of no exception.

A well-known pair exactly like Laloo is the Chinese boy A—Ke. There is a clay model of this boy in the Museum of the Royal College of Surgeons. Our knowledge of the A—Ke pair is based entirely on a description drawn up by J. Livingstone, a surgeon in Hong-Kong, in 1804. At that date A—Ke was aged 16. His mother died from the effects of labour. I have a manuscript copy of Livingstone's description, which contains a brief, but pathetic, report of the domestic relations of this poor lad; also a crayon portrait of him.

Now that the anatomy and relations of parasitic twins are better understood surgeons should be stimulated to remove them, and spare the autosite not only a dreadful life of bondage, but the disgust and ignominy of being exhibited for gain in public shows. That this is possible will be demonstrated in a later section of this lecture. In the case of Laloo we have a lad encumbered with a headless—acephalous—brother. A rarer form is a limbless parasite attached to an otherwise well-formed individual. Such a twin may be conveniently described as *capitate* (Fig. 4).

My knowledge of this rare variety of parasite rests on an engraving which Dr. Dan McKenzie found in a second-hand-book shop and sent to me. I have failed to find a detailed description of this rare example, but there is an engraving of him in the *Gentleman's Magazine*, 1777, xlvii, 424, and it is stated to be from a picture in the museum of Sir Hans Sloane. The *Journal* for the same year also contains, on page 572, an engraving of the conjoined twins Lazarus—Johannes Colloredo. These twins will be considered in a subsequent section.

FIG. 2.—The Siamese Twins Chang—Eng at the age of 16. They were born without difficulty, and died in 1874, aged 63. Chang died first.

TERATOID TWINS (TERATOMAS).

In order to emphasize the distinction between a parasitic foetus and a teratoma it may be stated that if the brother of Laloo (Fig. 3) or the limbless brother of James Poro (Fig. 4) were inside the abdomen of the autosite it would be called a teratoid-tumour—shortly, a teratoma. There would be this difference only: the teratoma would be enclosed, or sequestered, in a sac. Twins of this kind are of great interest to surgeons.

In 1808 Dr. G. W. Young described to the Medico-Chirurgical Society, London, "A foetus found in the abdomen of a boy." In this instance a large cyst was found in the belly of a male infant aged 12 months. A *post-mortem* examination was made, and the cyst, or bag, contained, in addition to a large quantity of fluid, the pelvis, lower limbs, and external genital organs of a foetus (Fig. 5).

The nature of the investment of a teratoma is of interest. Is it a persistent amnion? When an aseptic body, be it animal, vegetable, or metallic, or even a globule of oil, is introduced into the peritoneal cavity it becomes invested with a capsule. This is the most probable explanation of the bag which contained Young's boy. The capsule is adventitious. In recent years several such encysted imperfect foetuses have been removed by surgeons from the abdominal cavity of children and under conditions where the question of extrauterine gestation does not arise.

W. Roger Williams has, with conspicuous literary diligence, collected from current medical literature more than 100 examples of teratoid tumours and analysed them (*Medical Journal and Record*, New York, 1927).

For many years I have collected reliable reports of parasitic twins in order to grade them. What is set down in regard to the abdomen is also true of the head, thorax, and pelvis. There is this disquieting fact in regard to external teratomas of the sacral region—they are liable to be the seat of malignant disease.

One of the surprising specimens in my series is a black pigling, double in everything except its head. On close examination I saw evidence of reduplication in the maxillae, and hunted around to find the extra mandible. To my astonishment I found it in the pharynx, malformed but containing teeth, and hanging by a stalk from the pharyngeal surface of the sphenoid bone.

The interest of this little pig (which is preserved in the Teratological Gallery of the Royal College of Surgeons) is the support it gives to this opinion—*Pharyngeal teratomas are portions of the cephalic end of an undeveloped individual.*

A LIFE OF BONDAGE.

The psychology of conjoined twins is a curious problem; such couples, as well as individuals so unfortunate as to be hampered with a parasitic twin, should be objects of pity. Most of them are born to parents in poor circumstances, and when they survive their birth are apt to fall into the hands of crafty showmen who exhibit them for gain. Few can hope to be as lucky in respect to money as Chang—Eng.

They accumulated money, married, and lived comfortably on their farms in America. The Civil War ruined them. They went on show and recouped themselves. On the other hand, A—Ke's father belonged to the poorest class of Chinese husbandmen, and was content to let his encumbered son "on hire" for exhibition purposes. Ten cash (less than a penny sterling) was the price of admission. In Livingstone's record there is this note: "When A—Ke passes water, the parasite passes it at the same time, whether the urine is voided for necessity or to gratify the curiosity of strangers." In the case of Laloo, his headless and heedless parasitic brother voids his urine *independently without warning*, and usually over him, causing much discomfort day and night.

FIG. 3.—Laloo, the Hindu boy, aged 17, with his parasite brother. (*Tumours.*)

SURGERY AND CONJOINED TWINS.

In relation to conjoined twins, the thought uppermost in the minds of the parents is the hope of separating them by a surgical operation. In many instances this is impracticable. In the known instances where it has been carried out the life of one of the twins was sacrificed; and in a recent case (1927) both twins died. Dr. Boehm in 1861 separated conjoined twins—girls—a few days after birth. One died on the fourth day after operation; the other survived.

The Orissa twin sisters Radica—Doodica were shown in London in 1895. At their birth the inhabitants of the village, instigated by Brahmins, put the whole family in prison on the supposition that the twins were the incarnation of the devil. When I saw them they were attractive little children and danced daintily; they had silver bells on their necklaces, bracelets, and anklets. Eight years later Doodica developed signs of abdominal tuberculosis. Dr. Doyen, a French surgeon, separated them, and Radica survived.

In 1927 a male child, Karamet Hussain, was born in a village near Gujarkhana, India. Attached to the child was an acephalous parasite which, in its mode of attachment to the autosite, was the counterpart of Laloo (Fig. 3). When born the parasite had its arms around its brother's neck, and was born without difficulty. The mother was multiparous, aged 35.

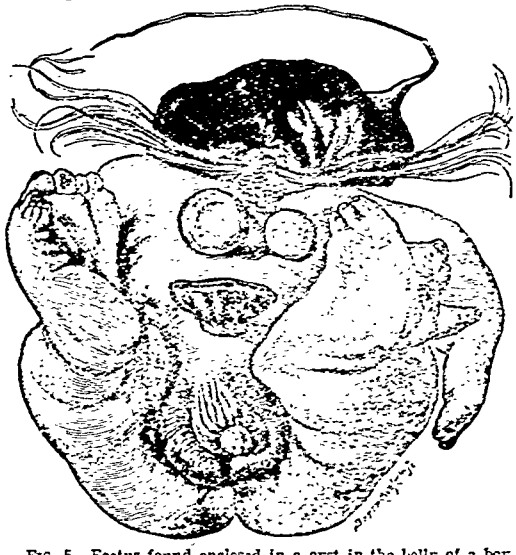

FIG. 5.—Foetus found enclosed in a cyst in the belly of a boy. When removed it was as rosy and as healthy as if alive. This specimen is preserved in the Teratological Collection at the Royal College of Surgeons.

A month after birth the parasite was growing rapidly, "and the parents were afraid that the life of the child would be troublesome," and sought the aid of surgery. Luckily aid was rendered by Captain D. D. Kapur of the I.M.S., and by a clever operation he relieved the child of its parasitic brother. The autosite was one month old at the time of the operation. Five months later the child was reported fit and well and growing nicely.

The leading facts of this case (*Lancet*, 1928, i, 24) should serve as a stimulus to surgeons and encourage them to spare the autosite not only a dreadful life of bondage, but the disgust and ignominy of life in a travelling menagerie.

In many conjoined twins surgical separation is barred by the anatomical conditions. This is the case with Violet—Daisy Hilton, born at Brighton in 1909. These twins were described by Dr. James A. Rooth as being united at the sacrum—pygopagous twins with a single anus. Their mother, panic-stricken when she saw her offspring, forsook them and fled. They were nursed by a foster-mother, who married a showman. They left England when 3 years of age and were exhibited in various countries. As the children grew the uniting band, mainly of skin, became flexible and allowed the girls to face each other so that they can "fight, play, or caress each other." One can sleep while the other plays: external genitals complete in each; anus common to both; micturition individual;

FIG. 4.—James Foro (born in Genoa, 1585).

surgical separation impracticable. The photograph represents them at the age of 18, and the showman speaks of their "health and beauty." They are intelligent, good musicians, can play the saxophone and other instruments, and they have acquired a comfortable fortune. A report more laconic and quaint would be difficult to conceive. Dr. James Rooth has furnished an excellent account of the delivery and infancy of the Brighton twins in the *British Medical Journal*, 1911, ii, 653.

Apart from the many disagreeables incidental to such unions, there is this dominating question: What will happen if one twin dies before the other?

Lazarus—Johannes Baptista Colloredò was born in Genoa in 1617. Each child was christened separately, and when

FIG. 6.—Violet-Daisy Hilton, the Brighton Twins.

they grew up were exhibited all over Europe. They were described by G. Bartholinus, professor of anatomy at Copenhagen. At that date the twins were 28. It is worth notice that Lazarus was of a just stature, courteous in deportment, and gallantly attired. He covered the body of his brother with a cloak, as presaging that when he died, he should also expire with the stink and putrefaction of his body. Lazarus therefore took the greatest care of his smaller brother. This is a good example of kindness for selfish reasons.

It is established that, as a rule, in the case of conjoined twins the death of one is quickly followed by the death of the companion. The fate of the pygopagous twins Rosa—Josepha Blazek, born at Prague and known throughout the world as the Bohemian Twins, is worth recording on account of its pathos. Josepha had pneumonia followed by catarrhal jaundice in Chicago in 1922, aged 44. Rosa refused to be separated from her sister. Josepha died first; Rosa died fifteen minutes later. Rosa's last wish was that she should be allowed to die with her sister. Rosa's son insisted on his mother's wish being respected, saying he preferred being an orphan to denying his mother's last request. At the age of 32 Rosa fell in love with the showman and conceived. She gave birth to a living child at Prague. The child was in Rosa's womb, but Josepha as well as Rosa had milk in her breasts (see *Tumours*, seventh edition, 1922, p. 502). A curious legal question arose because both women died intestate, and some relations of Josepha, the unmarried twin, claimed part of the estate.

LYMPHADENOID GOITRE AND ITS CLINICAL SIGNIFICANCE.

BY

G. SCOTT WILLIAMSON, M.D., AND INNES H. PEARSE, M.D.

(Dunn Laboratories, Professorial Units, St. Bartholomew's Hospital, London.)

WITH

A NOTE ON ITS ETIOLOGY IN RATS

BY

R. McCARRISON, C.I.E., K.H.P., M.D., F.R.C.P.,
BREVET COLONEL I.M.S.

(Nutritional Research Laboratories, Coonoor, South India.)

(With Special Plate.)

WHEN working on the histology of the thyroid in 1925 we found that there were two activities carried on by the normal gland.[1] This conclusion has since been substantiated by evidence drawn from several other sources—biochemical, biological, and clinical.[2,3] The two functions we refer to are: (1) The production of secretion proper; or what for greater precision may be called "lymphogenic" secretion. This secretion contains no thyroxin. (2) The accumulation of colloid—that is, iodo-colloid, which contains the thyroxin moiety of the thyroid products.

One of the features of the normal secretory process is the conspicuous activity of the reticulo-endothelial cells with the production of lymphocytes in the interfollicular lymph spaces of the thyroid gland units. It is this latter feature of the secretory process which calls for the specific designation "lymphogenic" secretion.

To the pathologist the knowledge of a specific process in the normal physiology of a gland must lead to search for the corresponding pathological condition in which undue strain falls upon that specific process. This, then, led us to look for a class of thyroid disorder in which the functional imbalance would lie in the over-production of lymphocytes during the secretory process of an otherwise normal thyroid gland. In the course of a review of about 4,000 goitres we were able to separate some glands answering to this description. These, when ranged in sequence, betrayed their own pathological sequelae—fibrosis and atrophy. Thus a pathological condition which had been obscure could now be discerned as a specific progressive disorder often associated with goitre. To this class of enlarged thyroid gland we gave the name "lymphadenoid goitre."* [5]

Goitres which essentially belong to the group of lymphadenoid goitres have been called by earlier observers "chronic inflammatory thyroiditis," "granulomatous thyroiditis," "endothelioma," "sarcoma," and also "Riedel's disease" or "woody thyroid," etc. Although these various designations fail to convey the true pathogenesis of this condition they do indicate its most striking features: (1) the lymphocytic activity which is typical of the early or progressive stages of the process, and (2) the fibrosis and atrophy which accompany its later stages.

The lymphocytic infiltration is peculiar in that it picks out the *specific* thyroid lymph spaces in a most delicate and selective fashion (Figs. 1, 4, and 5). In this manner

* The lymphadenoid process need not cause enlargement of the gland; indeed, it has been found as a progressive condition in senility.

(*By G. Scott Williamson, Innes H. Pearse, and R. McCarrison.*)

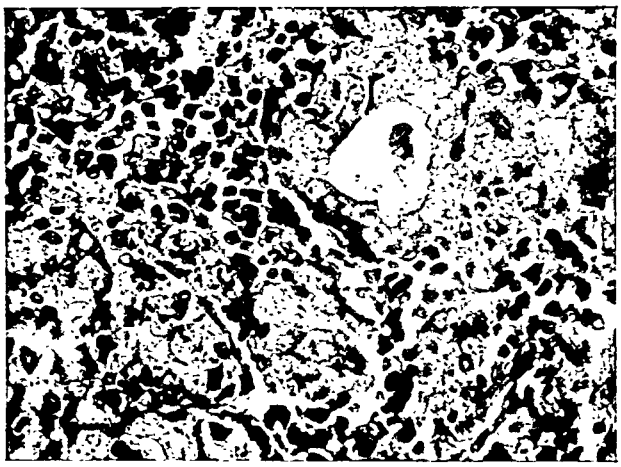

FIG. 1.—Section of a human thyroid showing the early changes in the lymphadenoid state. Lymphocytes fill the lymph sinusoids between the epithelial columns. Colloid is absent. The follicle is a "secretion" follicle.

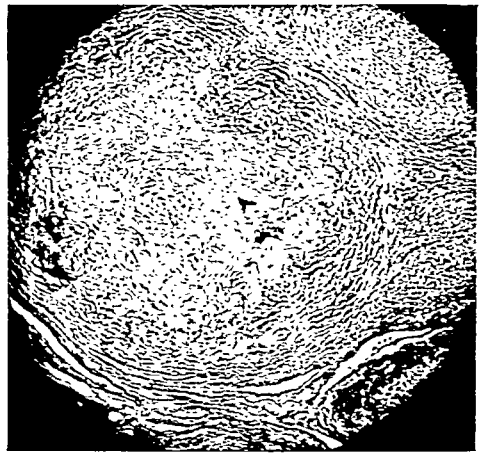

FIG. 2.—Later stage of the lymphadenoid process in a human thyroid. A whorl of fibrous tissue replaces a gland-unit.

FIG 3.—Section of a lymphadenoid thyroid of a man, aged 65, who died an accidental death and had no symptoms. The white opaque areas are foci of lymphogenesis.

it affords a beautiful picture of natural injection of the thyroid lymph sinusoid, and lends further confirmation to our conception of the essential nature of the thyroid gland units.

As the disease progresses the lymphogenesis becomes more and more active; lymphocytes begin to collect at the hilum of the gland-unit and to range themselves in a circular fashion around its circumference as they crowd in the perivascular lymph spaces about the capsule of the gland-units. With the increasingly active lymphogenesis the parenchyma, which is producing the lymphogenic secretion, becomes hyperplastic, and active mitosis appears in the epithelium. The overgrowth of the parenchyma is so great that, in some cases, islands of solid epithelial tissue fill the follicular spaces, from which by this time all secretion has been drained away. It is noteworthy that lymphocytes only accumulate in and about those gland-units wherein lymphogenic secretion is being formed. In the follicles where colloid is accumulating there is no perifollicular lymphocytosis. This characteristic feature of the condition can, of course, only be observed in earlier cases in the human subject and in the experimentally produced condition in rats; for, as the process advances, the abnormal lymphogenic activity claims the whole field, and colloid storage becomes inconsiderable. Exhaustion of the epithelium eventually ensues, and now, no longer able to produce secretion, it becomes atrophic.

Meanwhile the cells of the reticulo-endothelial system, so actively concerned in the lymphogenic process, also suffer; an insidious fibrosis invades this tissue, creeping along its course from the periphery of the lymph sinusoid towards the centre, until there ultimately appears a complete fibrous skeleton replacing the reticulo-endothelium of the affected gland-unit (Fig. 2). The process is not that of scar formation. It is one of replacement fibrosis beginning in the reticulo-endothelial system, which is the region of functional "strain," and finally involving also the isolated islands of exhausted epithelium. The picture produced by the end-result of this process is a characteristic and peculiar one, for the gland-unit is entirely replaced by fibrous tissue. An ever-increasing number of complete fibrous whorls are ultimately formed throughout the thyroid, each whorl representing what was originally an active gland-unit of thyroid tissue. This is the "woody" thyroid of Riedel's disease. Area after area of these whorled fibrous nodules become linked together by the late progressive fibrosis of the interlobular lymph channels, and the once much enlarged thyroid tends finally to shrink into a small knot of fibrous tissue, unrecognizable as a thyroid gland except for its position. This gland is the gland of myxoedema.

It is clear from the progressive and ordered chain of events in the pathology of lymphadenoid goitre that there was justification for postulating the association of this type of thyroid with some general, as yet undifferentiated, constitutional disorder, the terminal phase of which was myxoedema.[8]

The sequence of events which thus leads up to the gland of myxoedema had been already noted by Simmonds.[6] He also emphasized the fact that this sequence of events was to be found apart from myxoedema, but in evident association with hypothyroidism. A further survey by Simmonds showed conclusively that this was not a secondary event in infectious disease, but a very specific condition of the thyroid. The lymphogenesis, as he points out, is the cause of the fibrosis and atrophy, and not a reaction following primary atrophy of the gland. Tebbutt, in a study of the condition, confirms Simmonds's main conclusion, and definitely links the pathological process to a progressive hypothyroidism and ultimate myxoedema.[7] Carrying this a step further we have shown that lymphogenesis is a function of the normal thyroid, so that lymphadenoid goitre becomes an expression of a disturbance of the lymphogenic function of the gland. We may conclude that there is some specific general disturbance which expresses itself in the thyroid gland as lymphadenoid goitre. The general condition has as its clinical sequelae hypothyroidism and finally myxoedema. Spontaneous myxoedema is thus the termination of a general disease rather than the sequel of a local thyroiditis.

Clinicians have recently begun to recognize the condition, with the result that during the last eighteen months four out of the seven lymphadenoid goitres we have received from the operating theatre were diagnosed as such before operation. It is not for us to speak, however, of the full clinical syndrome; suffice it only to say that the tendency for lesser or greater degrees of myxoedema to accompany the goitre is already well recognized by the surgeons familiar with these cases. It is, indeed, likely that many cases exist in which no symptoms occur until the insidious fibrous atrophy induces a spontaneous myxoedema. Thyroid glands are occasionally found *post mortem* in which the early stages of the lymphadenoid condition are observable in the gland histology, but where there is no record of any coexisting symptoms (see also Simmonds). A figure is shown of one such gland taken from a man, aged 65, who died an accidental death (Fig. 3). It is certainly true that the typical gland attributed by the pathologist to myxoedema is identical with the gland of the terminal stage of lymphadenoid goitre.

Let us now turn to a consideration of the etiology of the condition. McCarrison has for many years been concerned to demonstrate that the thyroid gland plays an important part in the general metabolism and, further, that other workers, by confining their attention exclusively to the metabolism of iodine, have been taking too narrow a view of the thyroid function. He therefore set out to cause a goitre on a diet which contained iodine. He was guided in his choice of diet by the experience of his previous work, which showed the overwhelming influence of vitamins in the functional turnover of the lymphocytes in the intestine—or intestinal lymphogenesis.[8] He ultimately found a diet, containing an abundance of iodine, which gave rise to a disturbance of the lymphogenic function of the thyroid gland. In other words, McCarrison has produced experimentally a lymphadenoid goitre.

There is no room for doubt that the goitre produced in the rat and the goitre of the natural disease in man represent the same condition (Compare Fig. 1 with Figs. 4 and 5). The rat goitres represent the earlier stages, the greater number of human lymphadenoid glands encountered represent both the early and the later stages of an identical pathological process in the thyroid. Unless the human glands are completely replaced by fibrous tissue, areas can always be found somewhere in them in which the condition is still progressive; if the rat goitres are selected some will be found in which the characteristic fibrosis is already beginning to show. In the human subject the age at which the progressive symptoms show themselves is rarely before 45 years, while myxoedema, of course, occurs on an average a decade later. We have, then, every reason to expect that the terminal phase of lymphadenoid goitre can also be produced in rats, provided they can be kept alive sufficiently long under suitable experimental conditions.

NOTE ON THE EXPERIMENTAL PRODUCTION OF LYMPHADENOID GOITRE IN RATS.

BY

COLONEL R. McCARRISON, I.M.S.

The composition of the diets used in the experimental production of lymphadenoid goitre[9 10] in rats is as follows: American white flour, 72 to 82 parts; meat residue, 5 to 15 parts; olive oil, 8 parts; salt mixture, containing 0.45 per cent. of potassium iodide, 5 parts; distilled water *ad lib.* Various modifications of this diet, containing greater or lesser amounts of white flour, or having certain proportions of the white flour replaced by starch, have also been used.

Approximately 25 per cent. of young rats fed on diets of this composition, and confined in separate cages under conditions of the most scrupulous cleanliness, have exhibited goitres of various sizes at *post-mortem* examination. The goitres have been found in rats killed, or dying, as early as 75 days from the initiation of the experiments and as late as 165 days. They have occurred more frequently in females than in males. Macroscopically they are of glistening, fleshy appearance, bright or darkish red in colour, and vary in size from twice to five times that of the normal

thyroid. The isthmus is usually prominent, thickened, and broadened. One lobe is commonly more enlarged than the other; occasionally the enlargement is unilateral (Figs. 5 and 6).

Microscopically the goitres have presented in detail the appearances described by Williamson and Pearse as characteristic of the progressive stage of lymphadenoid goitre in the human subject. It is exceptional to find pronounced retrogressive changes—fibrosis and atrophy—in the rat goitres, although these have occasionally been encountered in relatively mild degree. Lymphadenoid changes have also been observed in glands presenting no obvious signs of enlargement; they were confined to certain areas in an otherwise apparently normal organ.[9 10 11]

Having had an opportunity recently to examine under the microscope sections of lymphadenoid goitre in man, side by side with others of experimentally produced lymphadenoid goitre in rats, the identity of the pathological state of the thyroid gland in man and in rats was apparent.

To the physician or surgeon who has to deal with goitre in the human subject the points of interest arising from these observations are: (1) lymphadenoid goitre occurs in man; it can be produced under experimental conditions in rats. (2) It arises in approximately 25 per cent. of young rats despite the adequate ingestion of iodine. (3) Deficiency of iodine in the food is certainly not the cause of lymphadenoid goitre as it occurs in rats; it is unlikely, therefore, to be the cause of lymphadenoid goitre as it occurs in man. (4) The basal factor in the causation of lymphadenoid goitre in rats is a dietetic one; it may reasonably be expected that the basal factor in its causation in man is likewise dietetic and of a like order. (5) Judging from experimental experience in rats the diets which are likely to be associated with lymphadenoid goitre in man are those composed largely of white flour or other vitamin-poor carbohydrate, vitamin-poor protein, and vitamin-poor fats and in which there is a paucity of fresh fruit and green leafy vegetables. In view of the almost universal use of white flour as the main staple of the dietary in Western countries, of the widespread use of vitamin-poor carbohydrate foods, of substitutes for butter which are relatively poor in vitamin A, of the use also of frozen and tinned meats, and of the small proportion of fresh fruit and green leafy vegetables in many people's dietaries, the etiological significance of the observations made on rats appears to me to be great.

THE PREVENTION AND EARLY DIAGNOSIS OF THE ACUTE ABDOMEN.*

BY

ZACHARY COPE, M.D., M.S., F.R.C.S.,

SURGEON TO ST. MARY'S HOSPITAL, AND TO THE BOLINGBROKE HOSPITAL, LONDON.

Though the title of my paper includes the early diagnosis of acute abdominal disease I wish to deal chiefly with the prevention of the acute abdomen. This convenient but slang term is generally taken to cover those acute conditions which come without warning, like a bolt from the blue, and it is seldom that a word is heard about measures for preventing such catastrophes. It is easy to see how this fatalistic attitude has arisen. In the course of practice the surgeon—who is largely responsible for current teaching—sees the patient in the throes of an acute calamity, the slighter premonitory features have been overshadowed by the catastrophic culmination, and there is frequently no strong inclination to prolong the time between diagnosis and operation in eliciting a meticulously accurate history of preliminary symptoms. As an example of this attitude I could cite a reference to a book published in 1914 by a famous London surgeon who, in describing a case of appendicitis, said "no surgeon of experience pays much regard to history." Until this attitude is replaced by one of very careful study of all the antecedents of the more acute conditions we cannot hope to diagnose early, much less prevent the disease.

I will first consider the extent to which it is possible to prevent the onset of any acute abdominal disease, and secondly how to prevent any acute condition which has actually started from reaching a catastrophic stage.

Until the exact pathology of the various abdominal conditions is known it is, of course, impossible to take exact precautions to prevent, but by a careful attention to symptoms it is occasionally possible to detect serious disease before it is acute. The different diseases vary greatly in their preventability, but it is worth while considering the question in each group of cases.

Take first the question of perforated gastric and duodenal ulcer. Is it possible to prevent perforation? If we only consider the acute ulcer which develops within a few days and precipitately perforates, the answer must be No; but when we recollect that the majority of ulcers which perforate are those of long standing the reply should be a modified affirmative. Chronic ulcers can now be diagnosed by means of the x rays in the great majority of cases, and if the correct treatment is adopted it should be possible to prevent perforation. If I am asked, What is the correct treatment—is it medical or surgical?—I cannot tell unless the type of ulcer is specified, and who is to carry out the treatment. Some ulcers are, I think, curable by the alkali method or by means of the duodenal tube; others hold out no hope of cure other than by surgery. The patient should be kept under treatment and supervision until the radiological evidence of ulcer has disappeared and the symptoms have subsided.

An ulcer may continue for many years without preventing the patient carrying out his duties, so constant supervision is necessary. A medical friend of mine, when a student with me, had a very severe melaena and all the symptoms of duodenal ulcer. He was advised to have an operation, but refused, and for twenty years managed a busy practice, though constantly ailing with dyspepsia and latterly having to give up from time to time. He was supposed to be rather neurotic by those who had not seen the melaena and did not know his character. Eighteen months ago (and twenty-two years after the melaena), while on a motor tour in Scotland, he had all the symptoms of perforation—pain, collapse, etc.—though fortunately the symptoms subsided with rest. I saw him a little later. An x-ray examination revealed very extreme pyloric stenosis and an ulcer crater in the duodenum. At the operation I found a mass of fibrous tissue all round the first part of the duodenum, with a recent perforation sealed over by omentum. Now this patient, who was known to have an ulcer, waited twenty years for his perforation, and but for the kindly offices of a bit of omentum might easily have succumbed. Correct treatment of the ulcer at an earlier date should have prevented this.

It is a common occurrence for there to be an exacerbation of symptoms for a few days before the perforation of a chronic ulcer, and this fact should be pointed out to all those who are known to have an ulcer and yet will not submit to give up the time necessary for the correct treatment to be carried out. Rest should be insisted upon in times of acute exacerbation of the symptoms.

The most common acute condition in the abdomen is appendicitis, and it is no exaggeration to say that any method of preventing that disease would not only save two thousand lives annually in this country, but would also more than halve the number of acute cases upon which the surgeon would need to operate. Appendicitis is no new disease, for in the College of Surgeons can be seen an

*An address delivered to the Croydon Division of the British Medical Association on October 16th, 1928.

account, written by John Hunter's own hand, of a *post-mortem* examination performed by him on the body of a colonel who had died with symptoms of intestinal obstruction, but in whose abdomen Hunter found only a perforated appendix with peritonitis. Yet it cannot be doubted, either on looking into old *post-mortem* records or examining the statistics of cases of appendicitis and peritonitis in later years, that the disease has become much more frequent in the last three decades. If we could but find the reason of this, prevention should be within our power. An exhaustive inquiry into the possible causes of this increase was made comparatively recently by Mr. Rendle Short. He came to the conclusion that the increase in the incidence of appendicitis was most likely due to some change in the dietary of the nation, but his evidence was against the common assumption that increased meat-eating had anything to do with the increase of the disease. By comparing the common articles of diet at the present time with those most in use before the great increase of appendicitis Short found that the chief change was a gradual diminution in the amount of cellulose-containing foods. He suggests that herein lies the cause of the greater predisposition to, and incidence of, appendicitis.

I think it will be allowed that appendicitis is a microbial disease which attacks certain people who are at the moment of attack in a state of diminished resistance to that infection. It will hardly be questioned that stagnation of the intestinal contents and the presence of much decomposing meat in the intestines are factors which would favour the growth of the infective organisms. It may be that cellulose-containing foods help to prevent stagnation of the intestinal contents, and they may possibly supply some vitamin which maintains resistance against the organisms. The moral to be deduced from this is that, so far as our knowledge goes at present, a predisposition to appendicitis would be lessened by (1) preventing constipation, (2) minimizing the amount of meat eaten, and (3) increasing the amount of food containing cellulose.

A fourth suggestion is to diminish the total amount of food taken. It is generally agreed that most people in this country eat more than is necessary, and often more than is good for them. Now it has been shown by Rendle Short that in institutions such as prisons and some children's homes, in which a low diet is given, the incidence of appendicitis is much lessened; while Horsley Gantt, in his very interesting account of the classes of disease which attacked the starved and neglected Bolshevist masses after the revolution in Russia, pointed out that appendicitis, cholecystitis, and similar inflammatory diseases of the intestinal tract almost disappeared, although most varieties of infective disease were rife at the time. I believe that appendicitis will once more diminish in frequency if some of the suggestions here given are followed up.

In considering diseases of the gall-bladder it is wise to deal separately with gall-stones and cholecystitis. It is not at all uncommon to find an inflamed gall-bladder without any gall-stones, and though gall-stones are usually accompanied by inflammation, that is not necessarily the case.

Cholecystitis apart from gall-stones has a close relationship with appendicitis. The two conditions are sometimes present together, and may occur at different times in the same person. It is quite likely that the same causes will tend to produce both diseases, and this is supported by the remarkable and parallel diminution in their incidence in Russia after the revolution. It has lately been shown that the infection of the gall-bladder may be primary in the wall of the viscus, a fact which testifies to the route of the infection being by way of the blood stream. In the prevention of cholecystitis and appendicitis, therefore, the importance of dealing with any focus of infection which might furnish a source of origin of organisms which could travel by the blood stream to the abdominal viscera must be remembered. The throat, mouth, and accessory sinuses should particularly be attended to.

The regular emptying of the gall-bladder is important if infection is to be prevented from obtaining a hold. Though the exact mechanism of the emptying of the viscus is not yet determined with certainty, there is strong evidence, furnished by Lyon and Meltzer, to show that the lower end of the common bile-duct is relaxed under the influence of magnesium sulphate applied round the orifice in the second part of the duodenum. Though some of the magnesium sulphate taken by the mouth may be altered in the stomach, yet it would appear rational to recommend the occasional taking of Epsom salts by those who are thought to be predisposed to disease of the gall-bladder.

The actual prevention of gall-stones depends not only upon the prevention of infection, but also on the prevention of hypercholesterinaemia and the avoidance of too much inspissation of the bile. Our knowledge of the formation and metabolism of cholesterin is at present too vague for any definite dietetic precautions to be taken with any chance of success of avoiding the formation of gall-stones. The encouragement of the flow of bile has been mentioned above.

Of the other common intra-abdominal inflammations salpingitis due to infection with the gonococcus is a preventable infection in theory, but practically the question is not such an easy one. The female is not usually infected from an acutely inflamed male urethra—for obvious reasons—but the trouble arises from the awakening of a chronic infection which has been latent in the prostate or seminal vesicles, or possibly in the crypts of the urethra itself. It is of the utmost importance, therefore, that all infections of the male genital tract should be as far as possible eradicated, and permission to marry should not be given unless and until the infection has been destroyed. I am aware that this is a counsel of perfection, for the channels of the genital tract are devious and labyrinthine, but at all events a series of stringent tests should be made to determine whether the infection due to the gonococcus is still present or not. Only in this way shall we be able to diminish the number of those cases of acute salpingitis following soon after marriage—cases of truly tragic import. It is not sufficient to examine the discharge obtained from the urethra after prostatic massage. An artificial congestion must be produced by passing a full-sized bougie, or by injecting into the prostatic urethra a few minims of a solution of silver nitrate, 5 grains to the ounce, and then examining the discharge. A big dose of vaccine should be given to induce a local reaction, and some have even recommended the administration of an amount of alcohol sufficient to produce urethral congestion. One examination should never suffice; several examinations at spaced intervals are necessary, and even when every examination has been made there can be no absolute certainty as to the absence of the organism, which may lurk in so many crannies in the tract. It is sometimes possible to destroy local foci of infection by means of the operating urethroscope.

Another form of acute infection which invades the female genital tract is that which leads to pneumococcal peritonitis. The work of Fraser and others makes it fairly clear that the pneumococcus gains entry through the vagina and Fallopian tubes, and since the condition chiefly attacks girls between 5 and 10 years of age we have a clear indication for prevention—that is, to promote local cleansing and hygienic measures so as to prevent the entry of the organism. The carrying out of these measures would devolve upon those who have the care of young children, and the medical man's part is to instruct those concerned.

The prevention of intestinal obstruction is impossible in some cases, problematical in others, but easily attainable in the majority of instances. This statement may cause surprise until it is recollected that the majority of cases of intestinal obstruction are due to the strangulation of external herniae. It is clearly easy to prevent strangulation of an external hernia by undertaking a radical cure of the condition. There are three or four factors which have a bearing on the question of operation in such cases—age, reducibility, control by a truss, the position of the hernia, and the general constitutional condition of the patient.

When a hernia is strangulated operation is undertaken whatever may be the age of the patient, and in any hernia which is irreducible, painful, or prone to attacks of subacute obstruction, operation should in general be recommended irrespective of age. It can be performed under gas and oxygen combined with local anaesthesia with very

little risk to the patient. There is no definite age at which it can dogmatically be said that the sufferer is too old for operation. If a hernia is easily reducible, and can readily be controlled by a truss, the danger of strangulation is greatly reduced, and there is no need to urge operation for such herniae in people over middle age who have no strenuous work to do. If the truss does not control, then the risk of operation is no greater than the risk of strangulation.

Of the three common kinds of hernia—inguinal, umbilical, and femoral—the first-mentioned is not quite so dangerous as the other two. The explanation of this depends probably on two factors. In the first place, umbilical and femoral herniae issue through rings with hard, fibrous margins, which have no "give" in them and make reduction more difficult; secondly, there is a greater nerve supply in the inguinal region, and strangulated herniae there are as a rule much more painful than those in the other situations. It is seldom possible to overlook a strangled inguinal hernia, but not so difficult for the patient and any unobservant person to miss a small strangled femoral hernia. Again, umbilical herniae usually occur in very fat people, and sometimes a small hernia may be embedded in the fat and hardly visible on the surface. There is all the more reason, therefore, to urge operation on even small herniae in the umbilical and femoral regions so as to prevent a strangulation which might easily be overlooked until too late. There is one exception to this statement—that is, the case of any enormous irreducible umbilical hernia of long standing occurring in a feeble patient. By operating and forcing the herniated mass into the general abdominal cavity the intra-abdominal pressure may be unduly increased, with considerable shock, embarrassment of respiration, and possibly fatal result.

Herniation through a weak scar of the abdominal wall is another preventable condition. It is not always possible to prevent the occurrence of a hernia in an operation scar—though much may be done by careful suturing and the imitation of drainage—but it is certainly possible to keep an eye on the scar for some time after operation, and to detect any weakness which may be remedied in time to prevent any risk of strangulation of the abdominal contents.

Intussusception is a disease of healthy babies who are attacked about weaning time, when the change from liquid to more solid food is taking place. Such strong babies are more likely to be favoured with "a little bit of what we have" at an earlier date than the more weakly, and this may sometimes account for its occurrence even from the fourth to the sixth month. Given an ileo-caecal region which is furnished with a longer mesentery than usual, an infant whose intestinal muscle is strong and equal to vigorous peristalsis, and a large food bolus sufficient to stimulate excessively the as yet uneducated ileum, and it is not difficult to see how an intussusception is produced. Indeed, it is strange that the condition is not more common. The only factor which can in any way be controlled is that of diet. Too sudden a change should not be made in the diet of a child aged from 6 to 18 months; let the transition from liquid to solid be graduated; also, do not let solid food be given too early simply because the child is stronger than usual. See, also, that the milk-clots in the child's stomach and intestine are made small by administering some sodium citrate by the mouth. Keep the bowels open so as to avoid constipation and straining.

Many forms of intestinal obstruction are almost impossible to prevent because the preliminary symptoms are so very vague and the physical changes so slight that nothing except actual vision can determine their importance. Cancerous stricture of the gut, peritoneal pouches causing intraperitoneal herniae, strangulation by Meckel's diverticulum, and a puckering of the mesentery and intestine by the attachment of a calcified lymph gland can hardly be prevented, though intra-abdominal adhesions following operations can, to a limited extent, be prevented by care in manipulation of the intestines, reduction of drainage to the minimum, peritonizing any raw surfaces, and attending to the details of suturing the abdominal wall.

In the case of recurring abdominal pain of a subacute colicky type, however, we have the barium x-ray examination to help in detecting any kink or stricture in the intestines, and though this method is very much less helpful than some enthusiasts would have us believe, yet sometimes it may lead us to operate and detect obstruction before it becomes acute.

Having considered a few measures which can be taken in order to prevent the onset of acute abdominal disease, I will now briefly comment on the early diagnosis of an acute condition which has started. I could not, even if I wished, do more than skim the surface of this very important problem, but I can best provoke discussion by making an extreme statement of the surgical attitude. *There should be a time limit for the making of a diagnosis in a case of acute abdominal disease.* I do not mean to suggest that it is always possible to diagnose a case in a few hours, but I do assert that any case of severe abdominal pain which lasts for more than six hours is serious enough to merit the calling in of a surgeon—not necessarily with a view to operation, but to exclude those forms of acute abdominal disease which need prompt operative intervention if they are to be successfully treated. I particularly put in the proviso about operation, for I believe the wise surgeon is recognized as much by his knowing when to operate as by his operative skill. I hope I am not presuming when I venture to think that the surgeon sees a much greater number of acute abdominal cases than any other branch of the profession, and if he is worth his salt he should be able to give a sound opinion on those cases.

I have often been astonished by the stoicism of patients, who will bear the most agonizing pain for many hours in the hope that it will subside spontaneously, and I have occasionally been surprised at the vicariously stoical attitude of some doctors when faced by a patient in pain. There are many acute abdominal pains for which a dose of morphine is the correct treatment—such, for example, as renal and biliary colic, gastric crises, diaphragmatic pleurisy with pain referred to the abdomen—but there are other conditions of an apparently similar nature for which to give a dose of morphine is, to say the least, an unwise, and, to say the most, a possibly fatal, procedure. It is generally possible to distinguish between these groups, and such a distinction should be made at as early a stage as may be done.

I have taken the time limit with reference to pain because that is the only constant symptom, but it is rare for that to be the only symptom. What I would insist upon is that any other common symptom is not to be regarded as essential. I have frequently had the statement made to me, "*I did not* think it could be serious because of the absence of a certain symptom"—the absent symptom varying according to the case. Now the common symptoms found in acute abdominal disease are: pain; nausea or vomiting; local tenderness; local muscular rigidity; distension; hyperaesthesia; shock; alteration of pulse, respiration, or temperature; furred tongue; constipation or obstipation; altered facies. There is hardly any absolutely constant symptom, but it may be safely asserted that pain is by far the most common, and is present in the vast majority of all acute abdominal conditions. All the others are most variable.

I think if I were asked which was the most important help in diagnosis after pain I should say altered facial appearance. I cannot describe the exact changes which the countenance undergoes, for this can only be learnt by experience, and some have great difficulty in acquiring this knowledge. To learn when a patient is really ill should be the first step in the diagnosis of acute abdominal disease, but it is astonishing how seldom this knowledge is acquired. Ward sisters often have more knowledge of this than the resident officer. There is one time, however, when the face does not help quite so much—that is, when the latent stage has supervened a few hours after the start of the disease.

Vomiting is frequently absent in appendicitis, often occurs only once immediately after the perforation of an ulcer, is not to be expected in obstruction of the large

bowel, and may even be absent in acute obstruction of the small intestine when gangrene quickly follows obstruction; it is not a constant symptom in the rupture of an ectopic gestation. Nausea is more constant, but not so striking a symptom.

Distension must never be waited for, and should not be present in the early stages except in obstruction of the large intestine. I well remember a man being sent to St. Mary's Hospital some years ago by a doctor who wrote: "Last night I thought this man very likely had a perforated ulcer, but he was not distended, so I left him alone: this morning he is distended, so I send him up to you."

Alteration of the pulse rate is of value when noted, but nearly every kind of acute abdominal disorder may be present without an appreciable alteration of the pulse. In some of the acute colics the pulse may be slowed; in perforated gastric or duodenal ulcer the pulse after two or three hours generally becomes quite normal; in intestinal obstruction of either the small or large intestine the pulse is frequently normal or slowed until toxaemia begins or unless there is severe shock on account of strangulation. In appendicitis I expect to find a normal pulse, unless (*a*) there is commencing peritonitis, or (*b*) the appendix is distended with toxic material. I have even known a normal pulse with acute pancreatitis, though I must admit that this is very exceptional.

I need hardly dwell on the *variability of temperature* in acute abdominal disease. A drop of several degrees accompanied by acute pain in the abdomen at once proclaims the occurrence of a catastrophe, however quickly the patient may regain a normal appearance. But many conditions cause no fall in temperature. Fever is absent in the acute obstructions, is moderate in amount and rather slow in onset in the peritoneal inflammations, and is high only in those conditions where infection is occurring in small cavities such as the pelvis of the kidney and the biliary ducts. I make it a rule in any case of acute abdomen with a temperature of 104° or 105° to turn first to the kidneys and then to the lungs and pleura.

Constipation is too vague a symptom to be of much use in early diagnosis. The same remark applies to furred tongue, though it is often possible to learn a lot by looking at the tongue.

An *increase in respiratory rate* must make one examine the lungs very carefully, but this increase quite often occurs in acute abdominal disease, so it is not of such great help.

Local muscular rigidity, though frequently referred to in the textbooks as a regular sign of appendicitis and peritonitis, should never be waited for. It is seldom present when the inflammation has not pierced through the walls of the appendix, and even when peritonitis has commenced muscular rigidity is absent when the inflammation affects a silent or undemonstrative part of the peritoneal cavity—for example, the pelvis or central part of the abdominal cavity. I wonder how many lives have been lost by ignorance of this simple fact.

We come, then, to the conclusion that the diagnosis of the presence of acute and serious abdominal disease is decided chiefly by the occurrence of pain—spontaneously complained of by the patient or elicited by local pressure on certain parts of the abdomen. The pain must be investigated from every standpoint—time of onset, character, duration, severity, position, variation in position, whether it occurs on breathing, passing urine, or defaecation. Finally, the practitioner should ask whether it is referred to any part other than the primary part, and observe how the patient turns over on to his side. Local tenderness must also be carefully sought; this examination is assisted by a careful study of the face. All other symptoms are observed, but it is generally possible to say whether the condition is serious or not by the simple observations I have described.

The doctor must make up his mind within six hours or less as to the seriousness of the condition. If he is doubtful he should not be ashamed to get a colleague to help in diagnosis. He must never procrastinate, for procrastination is the thief of lives.

TREATMENT OF ASTHMA BY RADIATION.*

BY

S. GILBERT SCOTT, M.R.C.S., L.R.C.P., D.M.R. AND E.CAMB.,

DIRECTOR OF THE RADIOLOGICAL DEPARTMENT OF THE LONDON HOSPITAL.

THIS disease, or rather symptom of disease, must still be regarded as an unsolved medical problem. As Professor Wild states: "Asthma is one of the most fascinating diseases for everyone except the patient." Theories have been advanced from time to time as to possible causes. The numerous so-called cures that are advocated simply indicate that no one "cure" is effective.

While not proposing to discuss the many different theories or even to advance a new one as the possible cause or causes of asthma, I will briefly outline one that is at present gaining ground, as it is helpful in explaining the effects obtained by radiation (*x* rays), administered by the method about to be described.

It is now generally accepted that asthma is not primarily a lung disease, but that some condition outside the lung is responsible for the spasm of the bronchial tubes. Abnormalities of the upper respiratory tract, such as nasal polypi; infection, such as sinusitis; chronic appendicitis; ovarian irritation; intestinal worms; the presence of cats, dogs, horses, feather cushions; the intake of certain foods, and many other agents, fantastic and otherwise, are known to give rise to an attack of asthma in different individuals. But should not these be looked upon rather as *triggers* that let off the asthmatical gun than as the primary causes of asthma? In more scientific language, do they not start a reflex, peculiar to asthmatical patients, in some organ or organs, which upsets or disturbs the metabolic or endocrine balance?—a somewhat nebulous term, but indicating a complex condition, which is best described as a loss of balance between the various ductless glands. The investigations of many workers tend to prove that one gland is, in some indefinable way, dependent on the quantity and quality of the secretion of another for its proper functioning. If a break occurs in this cycle, either a nerve reflex or otherwise, the whole balance is upset, and this is made manifest in many and various ways.

It is conceivable that each gland, when at fault, gives rise to its own particular set of clinical manifestations. Is it possible that in asthma the secretion of the suprarenal glands is defective? This somewhat speculative theory is mentioned here, for I believe that, in some manner, general radiation influences the secretion of the ductless glands. In other words, the beneficial results may be achieved by restoring the metabolic balance.

X rays have been used by many workers as a therapeutic agent in asthma, but the available literature on the subject shows that the results are, on the whole, disappointing. I believe two technical faults are responsible for this failure—*too small* a radiation field and *too large* a dose. The majority of authors treat only the thorax, using single front and back areas of about 10 by 15 cm. and the short wave (high voltage) therapy.[1] Others have found that some cases respond better if the spleen alone be radiated in the same way.[2] Even the skull has been radiated for this disease.

The important factors in the method of radiation about to be described are *the use of a large field and small dosage*. I wish to emphasize this combination, for, so far as I can find out by examining the literature on the subject, it has not been previously used in asthma.

As the beneficial results were discovered accidentally, it is difficult to say with certainty upon which organ or organs influence is being exercised. The whole trunk, back and front, is therefore irradiated, using the long ware therapy (low voltage). It is interesting to note that results have been obtained by radiation of the abdomen alone, but not by the radiation of the *thorax* only. The possible biological effects of a combined large field and small dosage have yet to be investigated, and the budding research worker should

*Read at the Second International Radiological Congress at Stockholm, 1928.

here find ample material to work upon. Might not the effects be analogous to those of sunlight carried to deeper structures? One might hesitate to bring forward yet another method for the treatment of asthma if it were not for the fact that the beneficial effects were accidentally discovered. The method, therefore, was not based on any preconceived theory; the beneficial results are undeniable.

It was while working on the problem of radiation in connexion with cancer that its effect upon asthma was first noticed. With the object of preventing metastases occurring in malignant disease, and with the possibility of stimulating Nature's defensive measures, I introduced the dual or open method of radiation some five years ago at the London Hospital. This general radiation of the whole trunk[3] has proved of such value that it is now given as a routine in all cases of cancer, in addition to any intensive local applications that may be necessary. While a patient was undergoing this treatment for malignant disease of the breast some three years ago she volunteered the statement that her asthma had thereby been cured. I was ignorant of the fact that she had been a martyr to this distressing complaint for some twenty years. The statement roused my interest, especially as there could be no question in her case of the results being due to suggestion. After considerable difficulty several cases of true asthma were recruited from among my friends. The results very soon convinced me that we had here a valuable therapeutic agent requiring investigation.

Being somewhat sceptical, it was some time before I felt justified in coming to the above conclusion. A policeman and a butcher finally turned the scale. The policeman had been discharged from the force, having been asthmatical for some ten years; his asthma had become chronic. He was blue in the face, with hardly enough breath to give his history. He came back the following week to all appearances a normal individual, and stated that he experienced relief twenty-four hours after the first treatment. He had been free from asthma for two years when he last reported himself, and was earning his living. The butcher's livelihood was threatened, as he was unable to enter the cold storage room without severe asthma; he also was cyanosed and distressed on presenting himself at the hospital. He reported after the third treatment that the cold storage room had no terrors for him.

A preliminary note on the technique was published in the *British Medical Journal* of June 5th, 1926 (p. 939). It is quite simple, once the importance of the combination of a large radiation field and small dosage is fully appreciated. Two Coolidge tubes, one focused on the back and the other on the front of the patient, so arranged that the rays cover the whole trunk, are energized by two separate installations, both tubes running at the same time. While this arrangement saves time the results are equally good if each side of the body is treated separately. The anterior tube, at 12 inches from the skin, is centred over the epigastrium, and arranged to cover an area from the chin to the symphysis pubis, and the posterior tube a corresponding area.

The short wave or high voltage therapy should *under no circumstances be used with this method*; serious damage to the patient may otherwise result. The voltage should never exceed 150,000 volts—in fact, some cases respond better if a still lower voltage is used. Aluminium filters can therefore be used with safety; 3 to 4 mm. thickness is all that is required, the latter being reserved for the heavy patients. A filter of 2 mm. will suffice when treating young children, with a correspondingly small dose.

It is strongly recommended that in addition to any indirect measurement of dosage, some *direct* method of measurement should always be utilized in low voltage work. In place of anything better, the Sabouraud pastille makes a satisfactory unit, but it *must be placed on the skin* and the tint read off by means of a tintometer. It should be noted that a quarter Sabouraud *B* tint, measured on the skin without a filter, is equal to a full erythema dose. A dose of 20 X through a 4 mm. aluminium filter, the maximum dose used in malignant disease, represents a double erythema dose to the skin, although it is found from actual experience that this gives rise to only a mild erythema.

The average dose used for an adult with asthma is 15 X per 3 mm. of aluminium, back and front of the trunk. This, using a 25 cm. spark-gap (points) and 8 mm. through the tube, takes on the average five minutes. In severe cases this dose is given twice a week for four doses, followed by a fortnight's rest, and then two laterally once a week. Milder cases receive the dose once a week for four doses, followed by two weeks' rest, and then two laterally once weekly. An occasional dose may be necessary after this course. Each case, however, must be treated on its merits to a certain degree, and the treatment modified accordingly.

The method has now been used for about three years. The preliminary note of the technique, published in the *British Medical Journal* of June 5th, 1926, was based on some twenty cases. The results now published are based on approximately 120 cases treated during the last two and a half years. Although the number is small, it includes all types—that is, unselected cases—and is sufficient to indicate that the treatment is of considerable therapeutic value.

To simplify matters the cases are grouped into three classes: Class A, asthma (A), subdivided into (*a*) paroxysmal, and (*b*) chronic. Class B, asthma with bronchitis (A–B). Class C, chronic bronchitis with asthma (B–A), with usually, emphysema. In Class A there were 31 paroxysmal and 19 chronic asthmatical cases treated; in Class B (A–B), 53 cases; in Class C (B–A), 18 cases. If we analyse these cases, the results are as follows:

	Cases Treated.	No Improvement.	Slight Improvement.	Slight Recurrence.	Good Results.
Class A					
(*a*) Paroxysmal ...	31	4*	—	4	21
(*b*) Chronic	19	—	4	2	13
Class B (A–B)	53	6	2	2	43
Class C (B–A)	18	3	1	2	12
Totals ...	121	15	7	10	89

* Two other paroxysmal patients gave up treatment owing to nausea.

The classification should not be taken too literally. For instance, paroxysmal asthma may become chronic at certain times of the year or in one locality. Again, it is not always easy to distinguish between chronic bronchitis with asthma, and chronic asthma.

The results in Class A—namely, patients with chronic bronchitis who have definite attacks of paroxysmal asthma in addition—are only given in relation to the effect of treatment on their asthma, although, in a few cases, the bronchitis was definitely benefited. Class B, made up of asthmatics who have periodic attacks of bronchitis, gives the best results, and in many cases the attacks of bronchitis seem to become less frequent and severe. Cardiac asthmas have not been included.

Several cases of chronic bronchitis with emphysema of long standing and with doubtful attacks of asthma were given a trial course of radiation. Although no apparent improvement was noted, these patients insist that they got relief, and come up at intervals for treatment.

Of the 121 cases treated, 89 derived definite benefit. I purposely do not use the term "cure." Not knowing the cause of asthma, we cannot say if we have removed it. Some of these may yet have recurrences, as it is but three months since their last treatment. With regard to permanency, the time is too short to give a definite opinion. The longest period of freedom from asthma was in a case of twenty years' standing; this patient has now been free for two and a half years. Many have been clear for over one year. Although the age of the patients does not appear to affect the initial results, there is a tendency to recurrence in those treated under 6 years of age. The average age of those treated is 40 years. One patient in the late sixties was able, after a course of radiation, to do without his nurse, who had attended him for five years. She applied to me for a new post!

It is important to make a careful radiological examination of the thorax in all cases. Definite fibrosis of the

roots of the lungs is present in practically all asthmatics, but three patients had definite evidence of pulmonary tuberculosis—two healed and one active—all unsuspected cases. The two former were treated with good result; the latter was sent back untreated and a haemorrhage occurred a few days later. The possibility of using this method of general radiation in pulmonary tuberculosis is under consideration.

The hilum fibrosis that is common in asthma is, I believe, a secondary condition, as no alteration could be detected even after radiation had been successful. The presence of "asthmatical triggers," such as nasal polypi, infections, etc., should be sought for and removed, if possible.

In considering the value of the results it must be remembered that practically all the cases treated by radiation were those which had tried all known methods, and had been driven to the use of anti-asthmatical cigarettes, injections of adrenaline, Tucker's inhaler, etc., for relief when they became really desperate. Many patients state that their asthma originated in their abdomen—that is, the attack was preceded by some form of abdominal discomfort or indigestion. This seems to disappear if radiation proves beneficial.

Several interesting but apparently unconnected observations have been made on the after-effects of general radiation, other than on asthma. Radiation sickness or nausea was observed to a very slight degree in most cases, but bore no relation to the results. Two patients, however, proved very susceptible to the reaction, and eventually stated that they preferred the complaint to the cure. In many cases looseness of the bowels, amounting even to diarrhoea, occurred during the course. A very noticeable result in quite a number of patients was a definite increase in weight. One put on 3 lb. each week for six weeks; another as much as a stone in a month, and 3 stones in three months. Patients often state that they feel considerably better in their general health, and that they are mentally brighter. One patient lost her sense of smell with the onset of asthma three years ago. This returned after the first dose, but for a week everything seemed to have a noxious odour, becoming normal at the end of that time. The condition of her nose had been previously passed as normal. In the early stages of treatment she had a slight recurrence of her asthma, and her sense of smell was again lost, only to return later. A doctor whose work was threatened on account of asthma became quite free from attacks, but stated that the treatment had put him entirely off smoking. As he grossly overdid it this was all to the good.

A few, subject to bronchitis as well as asthma (Class C), developed what appeared to be an acute attack of bronchitis soon after treatment had been started. This may, of course, be a mere coincidence, but I mention it as a possible sequel to the treatment, although no radiation fibrosis of the lungs was noted in any case. Several patients who had been treated for nasal catarrh unsuccessfully stated that this had disappeared with the attacks of asthma after radiation.

There are a few patients who respond well at first, but have a recurrence of their asthma, which is again benefited by further radiation, but is followed by yet another attack. In such cases further investigation for asthma "triggers," such as nasal polypi, sinusitis, etc., gave no clue to the cause of these recurrent attacks.

A much larger number of cases must, of course, be treated before the true therapeutic value of this method can be gauged, and for this reason it is not presented as a new cure for asthma. The results so far obtained at least indicate that we have here a valuable palliative agent worthy of further investigation and trial by the radiologist. An Asthma Research Council has recently been formed in England. Its objects are widespread. When funds are available they will cover research in all forms—the testing of the therapeutic value of various treatments, the collecting of statistics, and so forth. It should eventually prove of very great value towards creating order out of chaos.

A VOCAL COMPLICATION OF TONSILLECTOMY, AND ITS TREATMENT.

BY

SIR JAMES DUNDAS-GRANT, K.B.E., M.D., F.R.C.S.

THOSE who have examined many throats after tonsillectomy must have come across cases in which the action of the soft palate has been hampered by the tightening of its lower margin. This is caused by excess of the cicatricial contraction at the site of removal of the tonsils. By delicacy and care in the enucleation such contraction may be avoided, and when it is only slight it produces no ill effects, especially if the patient is not a singer. If, however, it is more than moderate it may, in a singer, interfere very seriously with the use of the voice. The breath is apt to escape behind the palate and the tone becomes less clear, while at the same time the enunciation of the explosive consonants (B, P, T, D, K, G) may become difficult, and they may be replaced by the resonants (M, N, NG). This is the so-called *dysfalia aperta*. The vocal sound may be accompanied by an audible bruit as the air escapes through the open though narrow passage behind the palate.

Apart from care in operating, it is well to start the patient on appropriate vocal and other exercises, to get the palate into play, soon after the throat has recovered from whatever reaction may have followed the operation—say, in about a week or ten days. This is of special importance in the case of the professional singer, in whom, indeed, the operation should only be carried out after full consideration. One writer on the subject states that he generally delegates the operation to other hands than his own when the subject is a singer. Comment is needless.

The chief remedial vocal exercise consists in singing vigorously and clearly on a convenient note the sound "m-bah!" The transition from the *m* to the *b* is effected by a drawing up of the soft palate, and this is obviously the movement which has to be preserved. If difficulty is experienced in making the transition without a break, the "*bah*" may be sung without a precedent *m*.

Another simple exercise is to sing merely the sound "*ah*," and test by means of a cold mirror under the nose whether air finds its way out through the nares, revealing to the patient's own eyes the existence of a defect which has to be rectified.

Still another useful proceeding is for the patient to blow vigorously through a very narrow tube, such as a fine Eustachian catheter or a pipe-stem, or even a straw, into a tumbler of water for as long as possible without taking a fresh breath.

The palate may also be exercised by means of a small quantity of innocuous oil, such as a light liquid vaseline, poured into the nose while the patient holds his head back and abstains from swallowing. If the palate is inefficient the liquid trickles into the pharynx and larynx and excites cough.

In illustration of these points I may quote the case of a young lady who had gained a valuable scholarship for singing, being endowed with a fine voice and exceptional musical ability. For doubtless excellent reasons her tonsils had been enucleated, but unfortunately her capacity for singing was seriously affected, and continued to be so. She was referred to me three months later, and when I saw her she was in great distress, as the authorities of the college were forced to decide that unless the emission of her voice returned to its normal condition they would have to withdraw her scholarship and give it to some other candidate.

She applied herself to the understanding of the instructions, and carried them out so successfully that, to her own great satisfaction and that of the authorities, she was able to retain her scholarship and to sing better than ever, benefiting incidentally from the removal of the tonsils, which had threatened to bring her career as a vocalist to an end.

I may in this connexion refer to the question of insufficiency of the palate, to which Brown Kelly has given particular attention. This usually takes the form of a wedge-shaped gap between the two halves of the hard palate. When this is present the soft palate is not so

readily drawn up as in normal circumstances, and the nasopharynx may not be so completely shut off from the mouth as is necessary for the production of a clear singing voice. In some cases compensation is afforded by a sphincter-like action of the constrictor fibres, or even by a pad of adenoid tissue or a prominence of the atlas vertebra. The condition is fairly uncommon, but it should be kept in mind when we contemplate clearing operations in those parts.

The removal of tonsils, even in singers, is sometimes obligatory, and always accompanied by some anxiety. I feel, however, that the anxiety is considerably diminished if we realize to what extent the possible disadvantages may be removed by the intelligent use of the exercises here described.

TREATMENT OF LUPUS ERYTHEMATOSUS WITH GOLD COMPOUNDS.

BY

J. H. TWISTON DAVIES, M.B.,

DERMATOLOGIST, ROYAL SUSSEX COUNTY HOSPITAL, BRIGHTON.

NOBODY who has attempted to treat a case of subacute lupus erythematosus with the methods available until quite recently can have failed to be impressed with the difficulty of such an undertaking. Prolonged rest in bed still holds the field as the most nearly infallible procedure, but it is obviously often impossible to persuade patients to take this drastic step.

In krysolgan I consider we have a drug which is almost specific and at the same time appears to be, with ordinary care, not dangerous. I record briefly my results in nine cases which have been treated since November, 1927, in the hope that they will encourage some of those who are still waiting to see which way this new therapeutic cat will jump. I have treated only moderately severe cases, for the reason that I did not care to pump foreign material into the general circulation of patients who were not overwhelmingly anxious to be cured, or in whom the disease was quiescent and of insignificant extent. Most of these had had previous treatment with quinine, rest, and various local applications, and some had already been treated for a short time with sanocrysin.

I may say at once that I have had no success with sanocrysin, possibly because I did not use the correct dosage. I started with 50 mg. and increased up to 250 mg. Whitehouse and Bechet,[1] who recorded four complete cures and eleven greatly improved out of thirty cases, regarded 100 mg. as a "rather large dose." I also understand that 1 gram is not considered unreasonable for the first dose in a case of active pulmonary tuberculosis. One patient received two injections of sanocrysin for a recent relapse of an old-standing lupus erythematosus, an extensive erythema centrifugum type; on her third visit, coinciding with a failure of the supply of the drug, I gave her 0.3 gram of novarsenobillon, to avoid disappointment, as she had come a long way from the country. Severe general and local reaction took place and was followed by the complete disappearance of the eruption, which has not recurred. I do not claim this case as a triumph for sanocrysin, and I mention it with the suggestion implied that intravenous injections of anything at all may cure certain cases of anything at all of an allergic nature, as is probably lupus erythematosus. However, I feel convinced in my own mind that I could not have done one-quarter as well in the following cases with any other form of treatment known to me.

I have used krysolgan in the following doses:

First Course: 0.075, 0.15, 0.375, 0.75, 0.75, 1, 1, and 1.25 grains.
Second Course: 0.75, 0.75, 1, 1, 1.5, 1.5, 1.5, and 2 grains.
Third Course: Four injections only of 1.5 grains each.

No unpleasant accidents occurred in a total of about 120 injections. The urine of each patient was examined three or four times, but albumin was never found, which is contrary to the experience of Nicolas and Schmitzer,[2] who found that albuminuria was constant after a total dose per course of 7 grains. The doses were given at weekly intervals with a four weeks' rest between courses.

For purposes of description I classify my cases into three groups according to the depth of involvement; one can guess roughly from the appearance of a patch what kind of a scar it will leave. Group I, erythema centrifugum type, leaving little or no scar. Group II, intermediate variety, leaving thin white supple scar. Group III, lupus erythemateux fixe, leaving disfiguring or warty scars.

Case 1.—A stableman, aged 43, with multiple patches of Type II; treated since June, 1926, with quinine; septic foci treated and various local remedies. He steadily became worse. Three injections of novarsenobillon produced no improvement; the same result followed twelve injections of sanocrysin. Krysolgan was started on February 24th, 1928; there was slight improvement only after one course, but no new lesions occurred. He was made much worse again by the untimely application of carbon dioxide snow. After a second course of krysolgan there was considerable improvement, but there were still about half the original number of lesions, and still active. There was no further progress after a third course; the final result being that the patient's condition was only slightly improved.

Case 2.—A restaurateuse, aged 59; tip of nose affected—Type II; she also had chilblains. The local application of carbon dioxide snow, after excluding oral sepsis, and four weeks' quinine treatment produced only temporary cure; she relapsed after exposure to the sun three weeks later. The lesion completely disappeared after the last injection of the first course of krysolgan. The chilblains were successfully treated with ext. thyroideum siccum, 1 grain twice daily. Still healed a month later, after half a second course had been given. Condition on June 8th, 1928—cured.

Case 3.—An unmarried woman, aged 28; relapse in thick white scar of previous lesion on the left cheek, also patches of Type I on neck and fingers. She showed slight improvement after one course of sanocrysin, but relapsed in a fortnight. She was nearly well after four injections of krysolgan, but two full courses were given before the patch on the cheek was completely healed. She was given a third course. Condition on June 8th, 1928—cured.

Case 4.—A single woman, aged 38, with active lupus erythematosus of Type III occupying the whole of the left side of the nose and part of the right batswing area. After the first course of krysolgan the whole lesion was white and showed no sign of activity. She returned after a fortnight with complete relapse, having been exposed to the sun. After waiting another fortnight she began a second course. The lesion was completely healed again after the third injection. She was still under treatment on August 30th, but appeared to be cured.

Case 5.—A nurse, aged 39, with extensive lesions of face and neck—Type I. After the first injection of krysolgan (0.25 grain) the eruption was only faintly visible. At the end of the first course only faint white patches of atrophy were to be seen. Four weeks later she was given a third course. Condition on July 30th, 1928—cured.

Case 6.—A married woman, aged 28, first seen on December 14th, 1926, with Type III lesions of tip of nose and both alae. These completely disappeared for eighteen months after rest in bed with quinine for ten weeks. After four injections of krysolgan she was much worse; it was therefore discontinued. There was no improvement after a course of sanocrysin. The lesion disappeared for two months after treatment with carbon dioxide snow, but relapsed again, and the disease is now extending. Result of treatment: no improvement; ? worse.

Case 7.—This patient, aged 71, edentulous, had extensive asymmetrical scarring and patches of alopecia with active lupus erythematosus of Type III at the edges of some of them. Patient complained of itching and a burning sensation. There had been no previous treatment. After one course of krysolgan no improvement was apparent, but relief of symptoms. A second course was given at the patient's request, and great improvement followed. A third course was given; there are now no signs of activity, and the scars seem to be thinner and more supple. Condition on July 20th, 1928—cured.

Case 8.—Patient, aged 58, was first seen on June 30th, 1926, with ulcerated, readily bleeding Type III lesions covering the whole of the nose and the left batswing area; there was also a patch on the back of the left hand. Cure for eleven months followed treatment with carbon dioxide snow and quinine. Patient returned on March 6th, 1928, with relapse on a small part of the original area. Removal of septic teeth, the administration of quinine, and further applications of carbon dioxide snow failed to bring relief. Slight improvement followed a first course of krysolgan, which was not, however, maintained through a six weeks' holiday. The condition was better after the second injection of the second course, but there was no further improvement at the end of the course. Condition on August 30th, 1928—very slight improvement. October 12th, after third course—cured.

Case 9.—A single woman, aged 38, with extensive lesions on the neck (Type I) and on the hands and feet (Type II). She had had relapses and spontaneous recoveries for five years. A severe attack in December, 1927, completely cleared up after treatment with krysolgan and rest in bed. She relapsed again in April, 1928. Krysolgan was recommenced in May. There was no improvement after doses of 0.375, 0.75, and 1 grain. She went away for a holiday, and returned complaining of severe pains in the back and thighs, which had followed shortly after the third injection. No organic basis could be found for these symptoms, but krysolgan was discontinued and the patient left the district. There was no improvement of the lupus erythematosus.

It may well be urged that mine is a very small series of cases, and that they have not been given nearly enough time in which to relapse, nevertheless any small success in the treatment of this disfiguring condition is acceptable to most of us, and if others are encouraged by this note to use the drug and to record their results its object will not have been missed.

THE DICK TEST IN SCARLET FEVER.

BY

WILLIAM BROWN, M.D., CH.B.GLASG.,

RESIDENT MEDICAL OFFICER, FALKIRK INFIRMARY.

IT has long been recognized that streptococci have some relationship to scarlet fever, but until the work of the Dicks no convincing evidence that the streptococcus was the primary etiological factor had been adduced. Their discovery, too, of a soluble exotoxin, by which clinical scarlet fever can be produced, and which can be used as a test of susceptibility to that disease, marks an epoch in the history of our knowledge of the disease.

The present investigation is concerned with the use of the Dick test in scarlet fever patients (*a*) on admission to hospital (273 cases), (*b*) at weekly intervals during residence in hospital (239 cases), (*c*) in a series of cases dismissed from hospital some time previously (159 cases). The material used was the "Wellcome" brand diluted scarlet fever toxin (test) and heated scarlet fever toxin (control). The test consists of an intradermal injection of 0.2 c.cm. of a 1 in 1,000 dilution of filtrate obtained from a broth culture of the *Streptococcus scarlatinae*. In the interpretation of the tests pseudo and positive reactions were counted as positive, and pseudo and negative reactions as negative. This is in accordance with the custom observed by other investigators.

In group (*b*) 152 cases were treated with anti-scarlatinal serum, and in group (*c*) 76 cases had been so treated. The serum used was Burroughs Wellcome and Company's anti-scarlatinal serum unconcentrated. In over 85 per cent. of these cases this did not exceed 10 c.cm. in amount.

DICK TESTS ON ADMISSION.

TABLE I.—*The Dick Test in 273 Cases of Scarlet Fever on Admission to Hospital.*

Day of Disease.	Total Cases.	Percentage Positive.
First	15	60.0
Second	69	73.5
Third	64	72.3
Fourth	55	63.0
Fifth	56	58.4
Sixth	11	72.7
Seventh to fourteenth	16	58.0
Fourteenth onwards	9	45.5

This table shows that, with the exception of the first day, there is a large percentage positive early in the disease, and that this percentage declines steadily until the sixth day, after which the numbers are too small to allow of trustworthy conclusions.

These figures compare favourably with those of Ker and his co-workers, who found 73.9 per cent. of positives during the first three days, and 68.6 per cent. in the period three to six days. Zingher obtained 98 per cent. positive during the first five days. In his paper on the subject Ker noted the disparity between his results and those of Zingher; he attributed this disparity to various causes, but especially to the greater dilution of toxin which he himself used. Lees, in an outbreak of scarlet fever in a school in Minnesota, found that fifteen out of forty-eight boys who developed scarlet fever gave a negative Dick test at the onset of symptoms. He used ten times the strength of toxin to re-test contacts, and did not obtain more positive reactions; he came to the conclusion that in this particular outbreak he was dealing with more than one strain of toxin. Various authors have reported cases of a patient being Dick-negative before developing scarlet fever. Robertson reports a case occurring in an epidemic. Nobel and Orel report one case seen by themselves and publish records of another case. I have observed the case of a nurse in hospital who was twice found to be Dick-negative and yet developed a typical attack of scarlet fever. Lees suggests that in any epidemic it would be advisable to isolate the particular strain of organism causing the disease before testing the contacts.

From the foregoing it will be seen that more accurate standardization of the toxin is necessary before complete reliability can be placed on results obtained from its use.

WEEKLY DICK TESTS.

This series of 239 cases is divided into two groups—namely, (*a*) 87 cases not treated with anti-scarlatinal serum; (*b*) 152 cases treated with anti-scarlatinal serum immediately after their first Dick test.

TABLE II.—*Weekly Dick Tests in Patients Not Treated by Serum.*

Week of Illness.	Total Number.	Percentage Positive.
First	79	69.6
Second	82	39.02
Third	84	23.57
Fourth	87	24.13
Fifth	85	27.06
Sixth	66	21.21
Seventh	42	19.05

This table shows that there is a decline in the number of positive reactions from the first week onwards, and that this decline is most marked between the first and second weeks. There is a slight and temporary increase in the number of positives during the fifth week.

These figures indicate a steady increase in immunity. A detailed analysis does not prove this for the individual. There are wide variations. Some patients rapidly become negative and remain so. Others are positive or negative on admission and remain so during their residence in hospital. Lastly, there is a group of patients, 13 in number, who are positive on admission, become negative, and subsequently become positive again. Zingher has stated that immunity to scarlet fever is mainly antitoxic in character. Little is known of the nature of antitoxin formation, but these facts would seem to indicate that individuals vary greatly in this capacity. This has been demonstrated by Lindsay and his co-workers, while Henry and Lewis have shown that the amount of antitoxin present in the blood of convalescent scarlet fever patients is considerably greater than in normal "resistant" controls.

TABLE III.—*Weekly Dick Tests in Patients Treated by Serum.*

Week of Disease.	Total Number.	Percentage Positive.
First	144	69.4
Second	151	11.92
Third	152	15.78
Fourth	152	16.44
Fifth	140	23.57
Sixth	106	32.02
Seventh	62	40.32

The two striking features of this table are the large decrease in the number of positive reactions from the first to the second week, and the gradual increase in the number of positives from the second week onwards. Both of these are attributable to the administration of anti-scarlatinal serum. The serum confers, in the majority of cases, an immediate passive immunity, which passes off to be replaced by the acquired immunity. Trask has shown that the amount of circulating toxin early in scarlet fever varies greatly in similar cases. It is probable that in some cases the amount of antitoxin given in the serum was completely neutralized by the circulating toxin. Since the percentage of positive reactions in the later weeks is greater in the cases treated by serum than in those not treated by serum, it may safely be assumed that the administration of serum at least delays the process of natural antitoxin formation.

OLD CASES.

It is well known that in the majority of cases one attack of scarlet fever protects the individual against a subsequent attack. It was determined to investigate the Dick reaction in patients who had been in hospital at some previous date.

1. Eighty-three patients who had had scarlet fever five years previously were Dick-tested. These cases had not been treated with anti-scarlatinal serum.

2. Seventy-six patients who had had scarlet fever nine months previously were Dick-tested. These cases had all been treated with anti-scarlatinal serum. This latter group automatically selected itself, as anti-scarlatinal serum had only been used for the first time on these cases.

Great care was taken in all these cases to ascertain by reference to hospital records that the attack of scarlet fever was genuine. Rosen and Korobicina call attention to this in one of their papers. Other workers on the results of the Dick test in patients with a history of scarlet fever have not stated that they took similar precautions.

1. In all of these 83 patients the Dick test was negative, thus indicating that they are no longer susceptible to scarlet fever. Rosen and Korobicina, in a series of 111 cases with a history of scarlet fever, obtained 23.4 per cent. of positives. However, in another series of 14 persons in whom the history was verified, they found that 2 only were positive and that these 2 had suffered from scarlet fever twenty and thirty-five years previously. It would seem, therefore, that where a history of scarlet fever is verified the Dick reaction is negative in practically every case, thus indicating immunity to scarlet fever.

2. Of the 76 cases treated by serum nine months previously, 8, or 10.52 per cent., gave a positive Dick reaction. These 8 patients had not developed their anti-toxic immunity. In the present state of our knowledge of immunity to scarlet fever it is impossible to state that the positive Dick test does indicate a lack of immunity to scarlet fever. Davies of Yale, from his investigations on a similar group of cases, considers that there may be some disadvantage in the use of anti-scarlatinal serum from the point of view of subsequent immunity to the disease. It may be that second attacks of scarlet fever will become more frequent. In this connexion it is interesting to note that the only case of a second attack of scarlet fever observed by myself during the course of this investigation occurred in a girl, 6 years of age, who had been treated with serum for a mild attack four months previously. Both attacks were undoubted, and the second more severe than the first. It is too early yet to look for confirmation of this aspect of the effect of serum administration.

This investigation was carried out in the County Fever Hospital, Motherwell, during the winter 1926–27, and I am much indebted to Dr. John Reid, the medical superintendent, for facilities provided and for much helpful criticism.

LACERATION OF THE ANTERIOR WALL OF THE FEMALE URETHRA AND ITS REPAIR.

BY

WILLIAM LEE, M.B., CH.B.LEEDS.

EXAMPLES of laceration of the posterior wall of the female urethra are relatively, though decreasingly, common in midwifery, and although tears of the anterior wall are not unknown yet the peculiarities of this case may make it worth recording.

A 5-para, aged 31, was admitted to hospital four weeks after delivery of her last child. Forceps were used and the child was stillborn. She had persistent incontinence of urine throughout her convalescence, and came into hospital with a provisional diagnosis of vesico-vaginal fistula. Albumin and pus were present in the urine.

Whilst under an anaesthetic the patient was placed in the lithotomy position. On examination the posterior wall of the urethra was found to be intact. The external urethral orifice was torn and ragged, and appeared to be dilated to about half an inch diameter. The little finger could easily be passed into the urethra, and the anterior wall was found to be torn for nearly an inch in length. This communicated with a large infected cavity behind the pubic arch, and the bare bone of the posterior aspect of the symphysis pubis could be palpated. It appeared as though the whole pelvic structures had been torn away from the pubes.

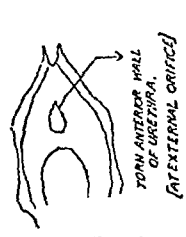

FIG. 1.

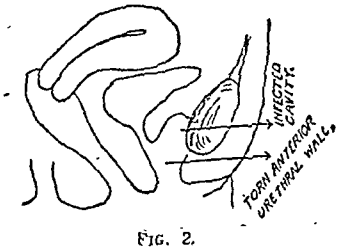

FIG. 2.

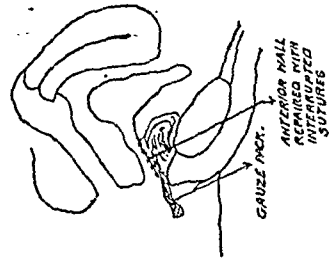

FIG. 3.

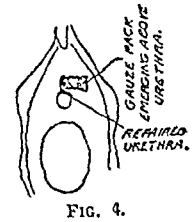

FIG. 4.

Diagrams of First Operation.

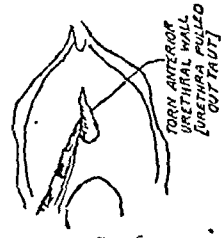

FIG. 5.

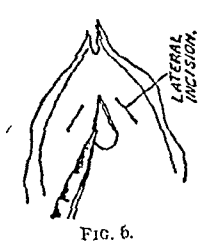

FIG. 6.

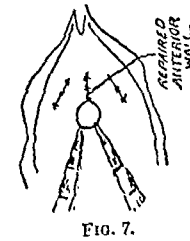

FIG. 7.

Diagrams of Second Operation.

An attempt was made to free the torn edges of the urethra, and this was repaired with interrupted catgut sutures. Three or four sutures were inserted anterior to the urethral wall in order to pull the lateral tissues somewhat together. A eusol gauze pack was placed in the cavity, the pack emerging at the vulva above the repaired urethral orifice. A self-retaining catheter was inserted into the bladder.

An evening rise in temperature occurred for four days, but was never more than 100.4°. The gauze pack was gradually decreased and the cavity closed completely, whilst the catheter was retained until the fifteenth day. For the following five days there was frequency and urgency of micturition, but no actual incontinence. Incontinence, however, did recur, and the patient was allowed to return home after two months in hospital.

She was readmitted two months later when her general condition was improved. The anterior wall of the urethra was found to be torn for about half an inch in length, and a great deal of contracted fibrous tissue was present round it. The urethra was pulled out taut and a small incision made along either side of the gaping urethra. The urethral walls were trimmed and brought together by means of interrupted catgut sutures. Two catgut sutures were put into the side wounds and a self-retaining catheter placed with some difficulty into the bladder. The catheter was retained for three days and then had to be removed. After a few days the patient had complete control over micturition; only occasional frequency occurred, and the anterior wall of the urethra healed perfectly.

I am indebted to the surgeon in charge, Dr. E. O. Croft, senior honorary surgeon to the Leeds Hospital for Women and Children, for permission to publish this case.

SURGICAL TREATMENT OF PULMONARY TUBERCULOSIS.

BY

BERNARD HUDSON, M.D., M.R.C.P.,

SWISS FEDERAL DIPLOMA,

MEDICAL SUPERINTENDENT, VICTORIA SANATORIUM, DAVOS-PLATZ.

(With Special Plate.)

THE two following cases illustrate the value of surgical treatment in pulmonary tuberculosis which has failed to respond to treatment by general methods.

CASE I.

A man, aged 33, was admitted in October, 1927, suffering from very extensive disease in the left lung. The patient obviously had long-standing disease, and had been in bed already for nearly a year before admission here. He was very ill, thin, with a considerable amount of sputum and cough, and thoroughly toxaemic. *X*-ray examination showed the left lung to be practically opaque, although signs of cavitation could just be detected in the upper lobe. *The temperature range was very consistent, always about* 100° to 101° F. each evening. Artificial pneumothorax had been attempted in England, but had failed owing to the presence of strong adhesions. It was attempted again here by me, with the same result. The condition of the right lung, although the apex was slightly affected, was very good. As the patient was obviously going downhill, a consultation was called with a view to the *advisability of surgical intervention.* A plastic operation was decided upon, and on November 4th an extrapleural thoracoplasty was performed in one sitting, under local anaesthesia, parts of every rib being removed.

The patient stood this very severe operation remarkably well, and six weeks after was able to get up and lead a quiet, ordinary life, for the first time for over a year. His condition after four months (March, 1928) was extremely good; he had gained two kilos in weight, and the sputum had almost ceased, what there was being tubercle negative. The temperature range was never higher than 99.2° F. (rectal) at night, and all symptoms of activity had disappeared. The patient returned to England, for urgent reasons, during the summer, and followed his profession (solicitor) in London without any ill effects at all. He returned to Davos in November, 1928, for the winter. His condition is now excellent; he weighs 86 kilograms, as against 73 a year ago. He has steadily improved since the operation.

CASE II.

A man, aged 24, was admitted in January, 1927, suffering from very widespread and active tuberculosis of the left lung, the upper lobe of the right lung being also slightly affected. The family history was particularly bad. With ordinary treatment the disease settled down to a certain extent, but was never really quiescent, and it became quite obvious that it was slowly spreading, and undermining the patient's constitution. An artificial pneumothorax was proposed six months previously, but the patient refused it, being desirous of trying the sanocrysin treatment. He had a course of this treatment with no result one way or the other. At length, in October, 1927, he consented to have an artificial pneumothorax attempted. The induction was a complete success. However, on radiographic examination after the first few fillings, it was seen that the collapse, although complete over the greater part of the lung, and at the base, was hindered at the apex by what appeared to be a strong fibrous adhesion, which was holding open a large lateral cavity. It was evident that this would not give way except by cauterization, and accordingly this was attempted on January 9th, 1928. On examination by the thoracoscope, it was seen that there were actually two large adhesions, one behind the other, each containing numerous small blood vessels. Two or three other thinner adhesions were also present.

The largest adhesion was first dealt with. A trocar was introduced by the side of the thoracoscope, and in order to obviate bleeding—a troublesome and most dangerous complication—a third of the largest adhesion was first coagulated by the diathermic cautery, and subsequently divided by the electric thermo-cautery. This procedure was continued for the middle third of the adhesion, and finally the last part was dealt with, the adhesion thus being completely divided without a single drop of blood escaping. At the same sitting a portion of the second big adhesion was treated in the same way, but, the operation having lasted about three hours, it was decided to complete the procedure at a later date. There was no reaction to speak of. Fillings were given twice weekly in order to provide as much room as possible and to stretch the adhesion, which was a very short and thick one. This and some smaller ones were dealt with a month later, in the same way as previously described, and complete collapse of the lung ensued.

The patient has never looked back, and he has had no complications (fluid, etc.) whatever. He has a filling every month, is in excellent general condition, and has gained many pounds in weight. He has no fever, and no cough or expectoration. I last saw him on November 29th. Fig. 1 shows the case after the induction of the artificial pneumothorax, but before the cauterization. It shows well the holding open of the cavity by adhesions. Fig. 2 shows the condition after the cauterization.

In the first case the ordinary treatment by rest in bed and climatic conditions proved useless, and artificial pneumothorax was impossible owing to the presence of massive adhesions. In the second case although artificial pneumothorax was performed successfully as regards the greater part of the lung, it was really unsuccessful because of the apical adhesions which held open the large cavity in the upper lobe. This partial collapse of the upper lobe was not only a hindrance to the patient's cure, but was a positive danger, owing to the presence of the widely open thin-walled cavity. In this case the operation of dividing the adhesions was extremely interesting owing to their great thickness and vascularity. The diathermic cautery was used with marked success, there being no bleeding either during the operation or subsequently.

I am indebted to Mr. P. G. Sutton, M.S.R., of the *X*-Ray Institute, Davos-Platz, for the radiographs.

MEDICAL, SURGICAL, OBSTETRICAL.

A NORMAL VENTRICULOGRAM.

(With Special Plate.)

THE case here described may be of some interest from the point of view of showing the normal appearance of the lateral ventricles, and the relationship of the third ventricle to the foregoing in a case of ventriculography.

The patient was a man in early middle life, who was admitted to the Maida Vale Hospital for Epilepsy and Paralysis complaining of headache and convulsions. On admission he was found to have nystagmus of the pupils, but the discs were clear. Examination of the central nervous system revealed the presence of deafness in the left ear, suggesting involvement of the eighth nerve. The tongue was protruded to the left, implicating the twelfth cranial nerve. The Wassermann reaction was negative in both the blood and the cerebro-spinal fluid.

Ventriculography, or the injection of air into the ventricles, was performed under local anaesthesia in the hope that a diagnosis might be obtained as regards the presence or absence of a cerebral tumour. Skiagrams were accordingly taken showing the ventricles anteriorly, posteriorly, and laterally. The anterior and posterior ventricles are alone referred to in this article.

In the anterior view of the ventricles the two anterior horns of the lateral ventricle are clearly seen. They are filled with air, and are closely approximated, with the third ventricle lying below. In the middle line the pineal body can be seen through the third ventricle.

In the posterior view of the ventricles it will be observed that the third ventricle has emptied itself into the lateral ventricles, and only the posterior horns of the lateral ventricles are seen; these are normally situated. The pineal body can be made out to be in the middle line.

I desire to thank Dr. W. Russell Brain for permission to use the clinical notes.

RAPID RECOVERY FROM PLEURO-PNEUMONIA.

THE arrest of lobar pneumonia with pleurisy within thirty hours of its onset seems to be a gratifying achievement and worthy of record.

I was recently called to see a man, aged 55, whom I had attended four years previously with double pneumonia and pleurisy; from this he nearly died, but eventually made a good recovery. On November 1st, 1928, he went for a motor drive in the country and fell asleep on the ground with his coat off. He retired to bed that night feeling perfectly well, but, after a few hours' sleep, he awoke and was very restless. A little later he had a rigor and vomited, and immediately complained of shortness of breath, with a stabbing pain over the lower part of the left side of the chest, laterally and in front. A similar pain was felt over the tip of the left shoulder, and his temperature was 101.2° F. I saw him at 9.30 that morning, when his respirations were short, quick, and painful. He coughed then for the first time and brought up a lump of mucus tinged with bright red blood, the sight of which confirmed his impression that another attack of pneumonia was beginning. Examination revealed signs of consolidation of the left base, diminished vocal fremitus, an impaired note up to the angle of the scapula, diminished air entry, and distant voice sounds; a fine pleuritic rub was heard over this area and extending to the front.

He was ordered hot linseed poultices every two hours, the first of which contained mustard, and cachets four-hourly, containing half a gram each of aspirin and diuretin, and 0.12 gram of quinine. The temperature and pulse rate remained constant all

day; the expectoration was scanty, but each time contained bright red blood. He began to feel rather better, the pain became less, and he sweated profusely, but the lung signs remained about the same. I ordered a Dover's powder for the night, but he did not sleep much and the temperature was 101.5° F. and the pulse 100. At 10 the next morning he felt much better, the temperature had fallen to just below normal, and the pulse was 76; he was hungry and asked for solid food. The signs at the left base were much as before, but there was also a small patch of distant bronchial breathing and bronchophony, with crackling râles about the affected area; the pleuritic rub was still present, but less distinct. The expectoration was now more abundant and bright red intimately mixed with mucus.

From this time he steadily improved, the temperature and pulse remained normal, the bronchial breathing and bronchophony gradually diminished, the crackling râles gave place to redux crepitations, and the lung slowly, but completely, cleared up. The expectoration, however, never became rusty, but remained bright red in diminishing quantity until November 7th, when the cough and expectoration ceased. Similar cachets were given at four-hourly intervals until the temperature dropped, and were continued three times a day until November 7th.

This appears to have been a typical case of lobar pneumonia with pleurisy, the treatment being started within six hours of the onset. The temperature and pulse fell to normal within thirty hours, and the lung signs improved so that the patient was able to leave his bed on November 11th. He was on full diet and enjoyed his food from November 6th.

FLEXNER DYSENTERY IN A TWO-DAY-OLD CHILD.

IN view of the age of the child this case seems to be of sufficient interest to warrant publication.

A multipara after a normal confinement gave birth to a male child. The boy was perfectly healthy at birth, and was fed on the breast. Forty-eight hours after birth he began to pass loose green stools, which contained mucus and a small amount of pus, and were streaked with blood. The number of stools was not excessive, averaging two or three daily. The temperature remained normal. A portion of stool was plated out on MacConkey's bile salt lactose agar, and gave practically a pure culture of a non-lactose fermenting Gram-negative bacillus. This organism was culturally identical with *B. dysenteriae* Flexner, and was agglutinated to full titre with a polyvalent Flexner [illegible]. Under suitable treatment the child made [illegible] and was transferred to the Aberdeen City [illegible].

The mother was regarded as the most likely source of infection, and a rectal swab was examined for the presence of dysentery organisms; *B. dysenteriae* Flexner was easily isolated. The mother had no symptoms of dysentery, and, owing to the fact that she was suffering from puerperal insanity, no history of a previous diarrhoeal condition could be elicited. She was suffering from hallucinations and delusions of persecution, and was transferred to a mental hospital.

We are indebted to Professor McKerron for permission to publish this case.

TWIN ABORTION FROM A UTERUS DIDELPHYS.

THE following details illustrate the point that, in the country, the inaccessibility of such instruments as one does not happen to be carrying when called in may sometimes render rather mystifying an otherwise relatively straightforward case.

A married woman, aged 26, whose periods had been regular till May 8th, and ceased from this date, had pains on September 15th; a carneous mole came away two days later. The bleeding after this was not at all excessive, and the pains ceased until, early on September 20th, far more severe pains than before set in; the patient became increasingly upset and exhausted, although there was scarcely any additional bleeding. Digital examination revealed a closed os, and when this was sufficiently dilated to admit a finger the walls of the uterus felt smooth and normal so far as they could be reached. Violent bearing-down pains, however, continued. A rectal examination showed that the uterus was somewhat retroflexed, and caused a brownish discharge to pass from the vagina. On a second vaginal examination the finger entered a dilating os, and at once felt membranes presenting. After the earlier negative examinations this seemed rather puzzling, but no speculum was available nearer than my surgery some miles away. A dead foetus of about three months' gestation was delivered with its membranes.

A *speculum* was now obtained, and displayed a septum dividing the vagina from a little above the vulva and the uterus into anterior and posterior positions. It was sufficiently flaccid in the vagina to fall against the normal vaginal wall, and thus allowed the finger to pass sometimes into the empty anterior uterus from which the mole had been expelled and sometimes into the posterior uterus in which pregnancy had advanced two months or so further.

AN UNUSUAL TUMOUR.

THE following account and illustration of a tumour of uncommon appearance may be of general interest. I should be interested to hear of any similar cases and their diagnoses.

A Basuto woman, aged 66, came to me for treatment for a large "swelling." On examination I found a huge tumour mass on the left side of the chest. The whole mass was dependent from the left supraclavicular region, where it was attached to the body by a comparatively narrow "neck" of skin.

The illustration gives an idea of the size and shape of this tumour. In consistency it was soft, almost fluid, and seemed to have fibrous bands running though it in a longitudinal direction. It was covered by loose skin, which in places had broken down, and there were several old scars at the most dependent part. Over the surface there ran large veins, which were varicose.

The patient stated that the tumour began as a small swelling in 1917, and had grown steadily since then. It gives rise to no pain, but the sheer bulk makes it unsightly and oppressive. I tried to persuade the patient to have the mass removed, but so far she has not come forward for operation.

My own provisional diagnosis is that it is a lipoma, but I should be glad to have the opinion of others with a wider experience.

AN UNUSUAL CASE OF DIPHTHERIA.

THE following case illustrates, not only a curious type of diphtheria, but also the importance of confirming the diagnosis of laryngeal swellings by scientific methods before undertaking an operation or embarking upon a definite line of treatment.

A healthy-looking man, aged 55, came to see me because he had been suffering from hoarseness of the voice for five weeks. This he attributed to public speaking, since he had never felt ill.

On examination of the larynx by the indirect method his left vocal cord was found to be swollen and irregular about its centre. This swelling was white, and of the same shade of colour as the rest of the surface of the vocal cords, which were normal. His upper air passages were otherwise healthy, and his doctor could find no signs of disease in other organs. A diagnosis of intrinsic carcinoma of the left vocal cord was made. I decided to confirm this by removing a piece for section before performing the operation of laryngo-fissure for the removal of a growth which appeared to be in a favourable position for easy and complete eradication.

Accordingly, a few days later, under a general anaesthetic, I removed a piece of the growth by the direct method with Paterson's forceps. On section this specimen was reported to be old-standing diphtherial membrane.

Reports of Societies.

A PARASITIC MONSTER.

AT a meeting of the North of England Obstetrical and Gynaecological Society in Liverpool, on December 14th, 1928, with the president, Mr. LEITH MURRAY, in the chair, Miss K. EDGECOMBE (Liverpool) showed a parasitic foetus removed from a female child; the patient had been apparently normal until the age of 6 months, at which time a swelling developed in the left groin, and grew rather rapidly during the next two months. There were no definite symptoms and no cachexia. Congenital sarcoma of the kidney was diagnosed, and the tumour was removed, but the child died of shock a few hours later.

The incision showed a cystic tumour lying behind the peritoneum, between the spleen and left kidney and below the pancreas. A considerable amount of mucoid fluid was removed by puncture, and the cyst was found to contain a partly developed foetus.

The foetus consisted essentially of two well-formed lower extremities, pelvis, and buttocks, three rudimentary upper extremities, and a face, the cranium being deficient. The whole foetus was covered by skin and vernix caseosa. The lower extremities were complete, showing feet, legs, thighs, and buttocks. The left foot had five toes with five nails, the second and third toes being fused; the right foot had four toes with no nails. The legs were flexed at the knee-joint and crossed, with the right leg on top of the left. The buttocks and nates were well formed, a dimple

presumably representing the anus. The vulva was well formed, the right labia were well seen, and were more prominent than those on the left side; a vestibule was present. The labia minora enclosed a cavity 7 mm. in length, 4 mm. wide, and 5 mm. deep, containing apertures presumably of the urethra and vagina. Above the pelvis there was a rudimentary abdomen; this was represented anteriorly by a deep groove, about 4 mm. in width, formed by the flexion of the head upon the pelvis and lower extremities. Posteriorly the back was well formed, extending upwards from the lower fold of the buttocks for 9 cm. Immediately above the back posteriorly and the groove-like abdomen anteriorly the head was situated. There was no thorax, but three upper extremities arose about the junction of the head and back. The right upper extremity arose from a groove between the head and the right side, 6 cm. above the right buttock; it consisted of a small wrist and a hand, on which there were four well-developed fingers, with nails, but there was no upper arm. There were two extremities on the left side; the lower one of these corresponded in position with the right hand, and consisted of a lower arm and hand with two fingers, but no nails. About 1 cm. above this the second right hand was situated, arising apparently from a groove in the head, and consisting of a hand with four well-formed fingers and nails, but no arm or forearm. The head comprised about half the foetal mass. It was acutely flexed on the abdomen, and rotated to the left side. The face was represented by a rounded fleshy protuberance on the left side, measuring 5 cm. in diameter, and separated from the rest of the head by a groove. A well-formed mouth, 1 cm. wide, was apparent in the centre of the face, showing two lips outside and definite upper and lower gums inside. There were no teeth. The other features were rudimentary, the nares being represented by two depressions, and the eyes by two similar depressions, above which, however, there were superciliary ridges with hair. The vault of the skull came behind the face, and consisted of a hairy scalp with no bony cranium. The scalp was defective in its upper portion, and was replaced by a white, glistening membrane attached to the wall of the sac. The inside of the skull was completely lined with vascular membrane, showing a well-marked tentorium cerebelli, but, owing to the deficiency of scalp, no falx cerebri. The skull had probably been filled with *fluid, and there was no evidence of brain substance. Immediately* behind the hairy scalp was a large, fleshy ridge, showing no definite structure, and probably corresponding to the posterior portion of the neck.

The whole foetus lay in a cyst, which was completely lined by two layers of membrane corresponding to chorion and amnion, and was attached to the surrounding structures of the host, being bounded by the diaphragm, spleen, pancreas, and kidney. The foetus had two attachments—one from the membranes forming the deficient scalp, fused with the membranous lining of the sac; the other was joined by means of a small cord from the abdominal groove to a rounded protuberance in the posterior wall of the sac. This protuberance was hollow, and contained a viscid mucoid material; it probably represented the remains of a yolk sac. The remainder of the wall of the sac was vascular, with ridges on its posterior surface. Lying immediately below and externally to the main cyst was a second smaller cyst, about 4 cm. in diameter. This contained viscid mucoid material resembling that from the yolk sac, but was apparently not connected with the main cyst. Sections had been made through various parts of the cyst and wall. The structure referred to as a cord showed a hollow vessel, resembling an artery from its thick, muscular wall, and containing red cells in its lumen but at a small part of its circumference it was lined by columnar epithelium, resembling vitelline duct: exactly similar epithelium was found lining the yolk sac. The *membranes were composed mainly of fibrous tissue, but here and* there a lining membrane of flattened epithelial cells, resembling epithelium from the foetal membranes, could be traced.

Miss Edgecombe said that radiograms showed no definite bone formation. The type of parasitic foetus was that described by Ballantyne as "gastro-parasitus." He had suggested that it was formed by the inclusion of the second twin in the first during the closure of the great anterior fissure. It was a very rare occurrence, only about thirty-five to forty of this type having been recorded. In the cases traced the parasite had been of the same sex as the autosite, which pointed to a uniovular origin. The parasite in these cases usually proved fatal to the autosite, either from operation or from pressure, but cases had been recorded with an external parasite where the host had lived for many years.

Torsion of the Pregnant Uterus.

Mr. LEYLAND ROBINSON and Dr. H. M. DUVALL reported jointly a case of torsion of the pregnant uterus during the eighth month in a primigravada, aged 38. The surgical anatomy of the specimen was demonstrated and the mechanism of rotation illustrated by diagrams and lantern slides.

The symptoms were atypical, but the case was regarded as one of concealed ante-partum haemorrhage, the chief clinical feature being the profound collapse which contraindicated operation. The patient died thirty hours after admission to hospital, and at the *post-mortem* examination it was found that the right gravid horn of a bicornuate uterus had undergone about 270 degrees of axial rotation. The left horn was small and not canalized, the tube being represented by the fimbriated extremity only and the ovary encased in a peritoneal fossa, somewhat resembling a teratological ovarian hydrocele. The left kidney was absent, although the corresponding suprarenal capsule was found *in situ*. There was no separation of the placenta and membranes, and the condition of the uterine muscle from the affected horn showed intense congestion but no interstitial haemorrhage. There was slight fibrosis in the liver and kidney, but no evidence of toxaemic change.

Investigation of the literature showed that this was a rare condition in the human subject and that the present case was, perhaps, the first to be recorded in England; it was, however, a common condition in veterinary obstetrics, and particularly affected the cow, which had a bicornuate uterus. From an analysis of the published cases, chiefly to be found in German literature, it was clear that torsion of the uterus was set up by three factors: (1) asymmetry, such as might be produced by the presence of tumours, or associated with a bicornuate or uni-cornuate maldevelopment of the uterus; (2) an unduly long cervix, often found with fibroids and occasionally in pregnancy, constituted a pedicle very prone to torsion, and thus acted as a strong predisposing factor; (3) irregular muscular action, due to falls and sudden movements, operated as the common exciting cause.

Sarcoma of the Uterus.

Dr. M. DATNOW (Liverpool) described a specimen showing sarcomatous change in a fibromyoma.

The patient, aged 51, had been married for twenty-six years and was a 12-para. The last child had been born in 1921. There had been amenorrhoea for about nine months before admission to hospital with a gradually enlarging abdominal tumour, which grew at about the rate of a normal pregnancy. The patient was rather pale; the abdomen was distended and gave the signs of free fluid. Arising out of the pelvis was a hard, irregular tumour reaching about half-way between the umbilicus and xiphisternum; this seemed to be movable from side to side. On vaginal examination the tumour was felt to be attached to the cervix, which was drawn very high up under the symphysis. A diagnosis was made of a malignant pelvic tumour and an exploratory laparotomy was suggested, but the patient refused operation and died two days later. At the necropsy the abdominal cavity was found to contain several pints of blood-stained fluid; the bleeding appeared to have come from the necrotic-looking part to which the omentum was adherent. The uterine cavity was elongated, but the endometrium was unbroken and there was no other sign of malignancy. Sections taken from the friable portions of the tumour were composed of cells of different size and shape; many were round, some elongated and spindle-shaped, and a large number were multi-nucleated giant cells. The nuclei were very active and stained well, and the whole afforded an undoubted picture of malignancy. At a distance from the breaking-down area the sections did not contain any evidence of malignancy, and merely showed advanced degeneration. The bluish-looking fibroid showed an increased number of blood vessels as well.

Dr. Datnow said that various authorities differed as to the incidence of malignant change in fibroid. St. Andrew Kynoch (*Archiv für Gynäkol.*) had stated that if all fibroids were examined systematically 4 per cent. would be found to be sarcomatous. Kelly and Cullen had reported seventeen instances of undoubted sarcomatous change in 1,400 cases, a little over 1 per cent. E. MacDonald (*Journ. Amer. Med. Assoc.*) found seven cases in 700. Most authorities seemed to think that the frequency was between 1 and 2 per cent. On studying the tumour cells with an oil-immersion lens many of the cells in the growth *had a morphological resemblance to muscle fibres.* Dr. Datnow thought that this was an example of malignant change of the muscular element, and resembled very closely the case illustrated in Kelly and Cullen's book, which they described as an undoubted instance of sarcomatous change of the myomatous tissue.

Dr. Datnow also showed a specimen of sarcoma of the body of the uterus.

An unmarried woman, aged 59 years, had always been healthy except for tuberculous glands of the neck when a child. The *menses commenced at the age of 16 and were quite regular up to* the menopause, which occurred at 48. On admission the patient complained of a yellow vaginal discharge which had persisted for two years and had never been blood-stained. For the last four months there had been persistent vomiting and also loss of weight. Examination revealed a slightly enlarged uterus, and a diagnosis of malignant disease of the body of the uterus was made, but owing to the absence of haemorrhage it was thought wisest first to dilate the cervix and procure a section for diagnosis. After passing the first few dilators some necrotic-looking material came away which was taken as diagnostic, and abdominal hysterectomy was performed. Subsequently the patient was treated with Rad.

receiving in all 0.4 gram. The patient, when last seen a month before the date of report, was quite well, except for slight pain in the right side and occasional attacks of vomiting. She had gained two stones in weight, and locally there was no evidence of recurrence. Sections of the growth were somewhat atypical, but suggested a round-celled sarcoma of rather rapid growth; several giant cells were also present.

Dr. Datnow said that the interest in the case lay in the fact that there was much constitutional disturbance, and the patient did not complain of the discharge until asked; in fact, she had been treated as a case of gastric carcinoma. In spite of the area of uterus involved it was not so enlarged as one would have expected.

A Hydrostatic Vaginal Plug.

Dr. E. FARQUHAR MURRAY (Newcastle) read a note on the hydrostatic vaginal plug. He expressed the view that vaginal plugging by wool or gauze in cases of accidental haemorrhage or placenta praevia damaged the mucous membrane of the vulva and vagina and predisposed to sepsis. Efficient vaginal plugging implied the use of a retractor and movement of the patient into the cross-bed or left lateral position. The hydrostatic vaginal plug avoided these difficulties. The plug consisted of a small balloon of the type which, when distended, became sausage-shaped. It was sterilized by boiling, and distended with weak lysol solution by means of a Higginson's syringe. The amount injected would naturally vary with the case, but in general twelve "pumps" would produce a mass the size of a baby's head, and twenty "pumps" a mass which would tightly fill a female bony pelvis. As the injection was made support was given at first by the levators, but slowly the balloon would protrude at the outlet, and this was essential if it was to be an efficient plug. A little practice soon indicated how much pressure at the vaginal vault was sufficient to produce suitable counter-pressure to a tight abdominal binder. When sufficient fluid had been injected the neck of the balloon was ligatured and the syringe was removed. A broad perineal pad kept the balloon in position. Its advantages were as follows: (1) When removed many hours later the mucous membrane was still glistening and undamaged. (2) It was possible by controlling the protrusion to lessen the internal pressure sufficiently to allow examination of the cervix; after which, if still required, the internal pressure could be easily re-established. (3) Its removal was extremely easy. (4) The insertion of the plug could be effected with a minimum of disturbance to the patient.

SEPARATION OF THE UPPER EPIPHYSIS OF THE FEMUR.

AT a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland, on December 7th, 1928, Mr. S. T. IRWIN read a paper on separation of the upper epiphysis of the femur.

Mr. Irwin briefly reviewed the literature, and explained that this displacement was rare as the result of gross violence; he then described a case in a girl aged 11 years 11 months.

A three months history of so-called rheumatism with pain and limp was followed by a fall on a grass tennis court. The accident produced complete loss of function, the girl being quite unable to put her weight on the limb. At first there was no shortening, but eversion of the foot, with displacement backwards of the trochanter, and swelling over the front of the joint were the prominent features. A week later there was shortening of 1/2 inch, and an *x*-ray examination revealed a typical separation of the capital epiphysis of the femur.

He based his paper on this case and on seven others which he had had under his care. The condition occurred in about 1 per cent. of orthopaedic cases. Among children between the ages of 10 and 15 with symptoms suggestive of tuberculosis of the hip one out of every two or three might be expected to afford an example of the condition. The age was significant. Males were more affected than females, and unilateral cases exceeded bilateral by three or four to one. Traumatism was the usual causal agent, but the non-traumatic form was not rare. The symptoms and signs included preliminary pain, a limp, eversion of the foot, flattening of the hip, and limitation of all movements, especially flexion and abduction. There was no general disturbance; syphilis and tubercle were not causal agents, but endocrine disturbance was common, especially in bilateral cases in which the injury was often unrecognized if there had been one. There was at first no deformity, but after traumatism or a gross exacerbation of the pain a displacement downwards of the epiphysis occurred. The displacement continued in a downward and backward direction, the proximal end of the neck travelling upwards and forwards. The slipping might continue for months or years, but it eventually became stabilized by the epiphysis attaching its distal surface to the inner and lower aspect of the neck. Later on the upper part of the neck became rounded off, and entered into the formation of the hip-joint. At this stage the well-known deformity of adolescent coxa vara was produced, suggested simultaneously by Kocher and Hofmeister, and fully described in 1912 by Elmslie; if uncorrected before stabilization serious disability ensued due to pain, and limitation of all movements, even to the extent of complete ankylosis. Treatment by manipulation was advocated for early cases in which the epiphysis was still mobile. In recent cases with fibrous stabilization Wilson's treatment by open intra-articular operation was mentioned; for fully developed coxa vara of adolescence Wilson's intra-articular operation or extra-articular osteotomy was advised. The poor prognosis in unreduced cases was emphasized, and early diagnosis before fixation of the deformity was advocated as the only method of getting good results. A table showing differential diagnosis was prepared to indicate a comparison between pseudo-coxalgia, tuberculosis of the hip, and displaced epiphysis. A series of lantern slides and a number of pathological specimens illustrative of the paper were exhibited; these included the clinical course of one reduced case in which accurate anatomical reduction was obtained by manipulation.

The PRESIDENT, in congratulating Mr. Irwin on his interesting communication, said that the diagnosis of these cases was singularly important. He asked if there was any definite muscular spasm associated with limitation of movement or if there was any elevation of temperature.

Mr. F. J. HENRY said that the principal difficulty in cases of epiphysitis about the hip-joint was early diagnosis. He had seen a number of cases of uncomplicated irritability of the hip, described as non-tuberculous osteitis, which he thought might have been a premonitory stage of epiphysitis. He was doubtful about the treatment of such cases, because he did not like the idea of immobilizing them for any length of time, and he wondered if the prevention of weight-bearing by calliper was sufficient. He mentioned a case of true fracture of the neck of the femur in a small child, which he thought might possibly have gone unrecognized as one of these slipped epiphysis cases.

Mr. HENRY MACAULEY referred to three cases of adolescent coxa vara, in which there was limitation of abduction, with a good deal of shortening in advanced cases. In these adolescent coxa vara cases the epiphysis was displaced downwards. In the early radiograms there was usually a valgus condition of the neck seen, and in later stages there was a flattening of the neck. He said that coxa vara was a bad name to describe a condition which was a deformity of the angle between the neck and shaft of the femur.

Mr. C. J. MACAULEY drew attention to certain points in connexion with two cases of slipped epiphysis. Both patients were less than 20 years old, and in both there was a history of violence. In one case there was distinct limitation of flexion in the hip, and free movement, except for abduction and internal rotation; there was also tilting of the pelvis. The fact that the boy was able to walk about for two hours after the injury indicated that the epiphysis could not have been completely separated. A radiological examination revealed the epiphysis half-way down the exposed surfaces of the neck of the femur. Under anaesthesia he flexed the hip strongly, internally rotated it, and there followed a distinct "snap" at the hip-joint.

The other case he treated by operation after manipulative treatment had failed: he opened the hip-joint through an anterior incision, and replaced the head. Then he applied plaster-of-Paris, and later walking calliper.

Mr. IRWIN, replying, said that muscular spasm was present in early stages, but he did not think that it accounted for the limitation of movement in this condition. In some cases there was extreme limitation of movement which he could not explain. He had seen cases of displacement of both femoral epiphyses with free movement. Treatment was not responsible for the amount of movement; in a number of cases under extension there was no change in the amount of mobility. He thought that the fact that the epiphysis was forced into the cotyloid notch might explain limitation of movement in some cases. He had had no cases of extreme deformity, because he received the cases early. He referred to the age limits of the condition, and said that Perthes's disease was not present after the age of 10; it was characterized by a growth along the cartilage in the direction of the great trochanter, a break in the continuity of which would produce definite changes characteristic of Perthe's disease or pseudo-coxalgia. After manipulation he found the prognosis definitely worse; unless the epiphysis was replaced arthritis would ensue. The question of the amount of shortening was interesting, and the amount remaining after reduction was very small compared with that in unreduced cases. He was doubtful of the results obtained after intra-articular operation, and thought that traumatism might occur thus inside the joint. Mr. Irwin added that non-tuberculous coxitis was not a premonitory coxa vara condition; in many of these cases staphylococci had been found.

Syphilitic Synovitis.

Mr. WILLIAM PEARSON showed a case of syphilitic synovitis.

The patient was a lad, aged 17, who presented none of the facial or other characteristics of congenital syphilis, and whose general health was good. When first seen he complained of a considerable swelling of the right knee-joint of five days' duration, and a larger similar swelling of the left knee, which appeared four days later, and caused some pain on attempted flexion. When at rest the joints were painless. There was no history of injury or gonorrhoea. Examination showed bilateral synovial effusion in the knee-joints. There was no tenderness or increased local heat. The right knee was moderately distended, yielding a "patellar tap"; the left knee was so tense that no "tap" could be elicited. Movements of the right knee were painless and almost full; those of the left knee were much restricted owing to the size of the effusion. Mr. Pearson said that the absence of any history of injury or gonorrhoea, the bilateral character and almost simultaneous onset, and the clinical features suggested the symmetrical serous synovitis of congenital syphilis; a blood examination yielded a fully positive Wassermann reaction. When shown the effusions had greatly diminished in size as a result of three weeks' rest, and the condition had been painless throughout.

Mr. C. J. MACAULEY said he had a similar case at present in a lad, aged 17, who came to him with chronic, rather pulpy, thickening of the left knee-joint. There was, however, no evidence of fluid; there was slight muscular wasting, and considerable limitation of flexion and extension. It appeared at first to be a tuberculous joint, but there was no increased local heat. On the following day the other knee-joint was examined, and found to be full of fluid. The difference between the two joints was that the first was thickened and the other showed a serous effusion. A Wassermann test gave a reaction of *plus* 3. The boy stated that he was a haemophilic. He was now getting better.

Mr. F. J. HENRY had had two similar cases in children. The swelling was bilateral in both, and there was a considerable lapse of time between the appearances in the two joints. The first patient, a girl, aged 7, had a large, pale effusion in the knee-joint; this was followed several months later by a similar condition in the other joint. At times the joint became perfectly dry, and a fortnight later the swelling would recur, with slight limitation of movement. Mr. Henry asked Mr. Pearson if he had noted any association between congenital syphilitic joints and interstitial keratitis.

Mr. PEARSON, replying, said that joint lesions in syphilis were extremely rare. The cases he had seen were types of arthritis secondary to synovitis, and there was osteosclerosis of the adjacent ends of bone. In these cases the disease seemed to have been continuing in the bone for years before the joint was affected; there was a nodular thickening of the gummatous type in the synovial membrane. These cases were sometimes associated with interstitial keratitis, but they were also accompanied by other signs—namely, the Hutchinson triad of symmetrical deafness, characteristic teeth, and interstitial keratitis.

Partial Colectomy.

Mr. J. L. KEEGAN showed two patients upon whom partial colectomy had been performed.

A woman, aged 52, was admitted to hospital with urgent symptoms of intestinal obstruction; she was collapsed, and vomited a brownish fluid; there was abdominal distension, a rapid pulse, and subnormal temperature. Caecostomy was performed on the following day; distension of the colon from the caecum to the top of the sigmoid was found, and a small lump was felt in the region of the sigmoid, with collapse of the bowel below. Three weeks later the abdomen was opened in mid-line, and a resection of the growth involving the bowel was performed, with end-to-end anastomosis. The caecostomy wound was not closed. Now, seven months after the operation, the patient was well, with daily movements of the bowel.

The second patient was a woman, aged 60, who, for six months before admission to hospital, had suffered from loss of appetite and wasting. There was no constipation till shortly before her acute illness fourteen days prior to admission, during which time she had abdominal pain and vomiting. Fourteen days prior to admission she was seized with abdominal pain, vomiting, and distension, and till her admission there was no motion. At operation the caecum was found to be so tense and distended that rupture was feared. Mr. Keegan punctured it to allow gas to escape, and, having carefully protected the peritoneum, the bowel was lifted into the wound, and a purse-string suture applied. It was then attached to the edges of the incision in the peritoneum, and through a stab wound a large rubber tube was inserted for about 2 inches in the centre of the area outlined by the purse-string. This being drawn tight, a second one was placed 1/4 inch outside the first, and the incision closed by silkworm gut above and below. Resection of the growth was performed about four weeks later, and an end-to-end anastomisis was performed. Now, more than two years since operation, the patient was quite well, with good appetite and daily motion.

Mr. Keegan concluded from his experience that the high mortality in intestinal obstruction was often due to tardiness in making a differential diagnosis; therefore laparotomy should be performed at the earliest possible moment. Caecostomy was an operation easy to perform; it gave immediate relief, arrested toxic absorption, and enabled the surgeon to operate in a comparatively aseptic area should he wish to resect the descending or sigmoid colon.

ARTIFICIAL TERMINATION OF PREGNANCY.

AT a meeting of the Hunterian Society, held on December 3rd, 1928, at Simpson's Restaurant, with the president, Dr. WESTERMAN, in the chair, Mr. C. LANE-ROBERTS and Mr. A. C. MACALISTER opened a discussion on the artificial termination of pregnancy. Mr. Lane-Roberts divided conditions requiring such interference into three groups—namely, disproportion, conditions threatening the life of the mother, and those threatening the life of the foetus. Cases of disproportion were best treated in an institution, and while induction of labour was often advisable natural delivery might occur, and carried a lower foetal mortality. In eclampsia there was a tendency to use hypnotics and await natural delivery rather than to induce labour. Heart disease was dangerous especially in the first half of pregnancy; if the condition of the mother was serious towards the end of pregnancy the best procedure was Caesarean section under spinal anaesthesia. The speaker hoped that the hormone oestrin would soon be available as a means of inducing delivery. Mr. A. C. Macalister said that the law had nothing to say on the subject of the artificial termination of pregnancy which could not be left to one's conscience; there were very few indications for

this procedure, which was rare in hospital practice, but common in private practice. In general, interference with pregnancy was called for only when the pregnancy endangered the life of the mother. In Tsarist Russia abortion was illegal, and was liable to be followed by exile to Siberia of the mother and the abortionist concerned; in the Russia of to-day this operation could be carried out by any reputable doctor, and special hospitals were provided for the purpose. The number of such operations carried out had increased by some 600 per cent., while the incidence of infection in such cases had fallen to about 4 per cent. Some people denied the existence of pernicious vomiting of pregnancy, others regarded it, in its early stages, as neurotic in origin, in its later stages as toxic. If such vomiting was followed by jaundice or haematemesis the pregnancy should be terminated. In cases of heart disease little benefit could be expected from a termination of the pregnancy; it was better to allow it to proceed to term, and then do Caesarean section and remove the Fallopian tubes. A history of puerperal insanity was not an indication for interference with pregnancy; such insanity was usually due to preventable causes.

PERIODICITY IN DISEASE PREVALENCE.

AT a meeting of the Royal Statistical Society on December 18th, 1928, Mr. H. E. SOPER of the National Institute of Medical Research read a paper on the interpretation of periodicity in disease prevalence.

Mr. Soper said that the fact that epidemic diseases often came in the manner of surges, attended with great inconvenience and fraught with many special dangers when at their height, should be sufficient incentive for a close study of the fluctuations in disease prevalence. Many attempts to account for the periodic nature of the visitations of sickness had from time to time been made. It was true that the surmised mechanism of contagion, with its incalculable chances, might appear to give the lie to any possibility of a law being found which the epidemic would follow in directing its course; yet the stream flowed on through the tumult of eddies, and the fact that in a disease like measles the upheavals presented certain remarkable regularities could be taken as a challenge and a spur to the attack of the evasive problem.

Among the theories put forward to account for epidemic recurrence that most favoured presented a picture of a rise and fall in the new cases of a contagious disease as consequent upon a glut and dearth of susceptible persons; for, clearly, if there were a limit to the numbers who could contract the disease, the action might be supposed to go after the manner of a pendulum, where, as the energy of flow became exhausted, the energy of potential activity was stored up, to be released again when motion recommenced. The stored energy was the accumulation of susceptible children, by birth.

In a paper read before the Royal Statistical Society this view of the origin of the surgings of measles epidemics was taken and carried to a point a little beyond that already reached by the investigations of Sir William Hamer. It was shown, in fact, by arithmetic and algebra that a simple supposition in regard to the delayed or lapsing infectivity of an infected person, combined with a supposition of a constant inflow by birth of susceptible children, led, by invoking the statistico-chemical law known as "mass action," to an ever-sustained periodic wave, or swing of the epidemic pendulum, whose period could be interpreted. These idealized waves did not, however, give a very true replica of the curve of monthly cases of measles as presented by an actual chart, which (as shown by diagrams relating to Glasgow given in the paper) appeared to have the elements of order and chance somewhat cunningly interwoven.

Mr. Soper demonstrated that curves very similar in appearance to the curves of measles cases in Glasgow would be the foreseeable consequence of combining the natural epidemic swing with a forced seasonal impulse of a certain form, and that the form was one whose maximum coincided with fair truth with the time of assembly of schools after the summer vacation.

Reviews.

STUDIES ON MALARIA.

SIR RONALD ROSS'S *Studies on Malaria*[1] has been written to include in a small compass the essentials of the author's classical investigations from 1895 onwards, and it contains the essence of his larger *Memoirs* in a convenient and less expensive form. The first three chapters give a brief account of his researches in India from 1895 to 1898, which first established the development of human malarial parasites in the stomach of "dapple-winged" mosquitos (anopheles) in 1897, and the full development of the closely allied proteosoma of sparrows in mosquitos and infection through the salivary glands when they bit an uninfected bird in the following year. These investigations were unfortunately interrupted by a transfer in 1897 when war broke out on the Indian frontier, and by an investigation on kala-azar in the next year, and he was consequently prevented from tracing the full development of the human malaria in the anopheles, although he quickly did so in Freetown, Sierra Leone, a year later at the first opportunity. In the meantime, Italian workers had followed up his original discovery of the early stages in the anopheles, and completed the cycle on the lines he had demonstrated in the case of sparrow's proteosoma, and the longest chapter in the book is devoted to demonstrating his priority. As Sir Ronald Ross himself points out that the award to him of the Nobel Prize for his work on malaria, after a full investigation, sufficed once and for all to establish his claims, it is to be hoped that in a future edition this chapter will be omitted to make room for a fuller description of his early epoch-making researches, of which a much more graphic account is to be found in the author's *Memoirs* than in the present work. Most of the remaining two-thirds of the book describes the author's practical studies on malaria prevention in Freetown, Ismailia, Greece, Mauritius, and other countries, to which he has devoted so much labour; it reveals both the triumph of Ismailia and not unnatural disappointment at the failure of parts of our scattered Empire to reduce malaria as rapidly as he had hoped through the application of his methods of mosquito destruction. The author's extensive mathematical studies are frequently mentioned, but for accounts of his literary and poetic contributions his *Memoirs* must be turned to. The last chapter gives a lucid summary of the main facts about malaria, and the lay reader will find it easier to follow the earlier portions if he reads this account first. Portraits of Patrick Manson, whose help the author acknowledges, and of other workers on malaria are included in the volume, which affords a clear picture of a remarkable piece of medical research and of the many-sided genius of the man who accomplished it to the honour of English medicine.

LIPIODOL.

THE use of the iodized oil known as lipiodol during the last few years has grown extensively, and it was well recognized that the time was ripe for the appearance of an authoritative textbook on the subject. It is particularly gratifying that the two originators of the use of this substance, Professor J. A. SICARD and Dr. J. FORESTIER, have been able to write a large volume on diagnosis and treatment by lipiodol.[2] Their bibliography extends over sixty-six pages, and this gives a clear indication of the comprehensiveness of their work. The composition and properties of lipiodol are first dealt with, followed by an account of the methods employed, with general indications and contra-indications. Then the various diagnostic uses of lipiodol are described in detail: the intraspinal and epidural routes for its introduction in diseases of the nervous system come first, followed by an account of its use in the chest, genito-urinary passages, blood vessels, nasal sinuses, digestive

[1] *Studies on Malaria.* By Colonel Sir Ronald Ross, K.C.B., K.C.M.G., F.R.S., Nobel X Laureate. London: J. Murray. 1928. (Cr. 8vo, pp. xi + 196; 4 plates. 5s. net.)

[2] *Diagnostic et Thérapeutique par le Lipiodol.* Par J. A. Sicard et J. Forestier. Paris: Masson et Cie. 1928. (Med. 8vo, pp. 370; 49 figures. 50 fr. sans majoration.)

tract, and other less important situations. Finally, there is an interesting section on the therapeutic uses of lipiodol, principally for certain muscular and joint affections, where it undoubtedly appears to be of value in relieving pain. The diagnostic use of lipiodol in diseases of the nervous system is dealt with in most detail, and the localization of the exact position of spinal tumours by the combined use of ordinary lipiodol from above and a special "light" ascending mixture of lipiodol and olive oil from below, represents one of the very important advances which the use of this substance has made possible. The volume has been printed on a good quality glazed paper, which has allowed of the reproduction of *x*-ray photographs in the body of the book. These are without exception very good and well chosen. Indeed, the only fault to be found in this excellent and authoritative work is the absence of an index—an unfortunate omission all too common in books produced in France.

Dr. F. G. CHANDLER and Dr. W. BURTON WOOD have written a little book on *Lipiodol in the Diagnosis of Thoracic Disease*,[3] consisting of 133 pages of text and forty-seven illustrations grouped together at the end. They describe the various methods of using lipiodol in chest diagnosis, favouring the crico-thyroid membrane route as "on the whole most satisfactory," but they omit to mention an important point in the technique, which is the incision of the skin by a scalpel before the trocar and cannula is introduced. The dangers associated with the use of lipiodol are well set out in a short chapter, and the point that curiosity alone is not an indication for its use is emphasized. The section on interpretation of *x*-ray photographs of the chest after the use of lipiodol is unfortunately separated from the very good examples grouped at the end of the book, and is probably for this reason shorter than its importance would seem to warrant.

PROBLEMS OF THE CIRCULATION.

THE reader who looks for new observations in the Proceedings of the German Society for the Study of the Circulation[4] will be disappointed, but he will find several interesting discussions of some of the problems of the circulation. The papers read at the meetings of the society are grouped so that a small number of subjects are somewhat widely discussed from a multiplicity of aspects. The old problems of congestive cardiac failure are the subject of nine contributions. The mechanics of the blood distribution in this condition is not discussed, and one wonders if those who busy themselves with cardiac failure have sufficiently paused to consider why the venous side of the circulation becomes congested, and whether the raised venous pressure is a sequence to a failing heart or a reaction to its consequences. Eppinger directs attention to the peripheral part of the circulation where the functions of the blood are performed, and it may well be that there is to be sought the answer to our question. Dietrich supposes that the changes in the heart found at death from cardiac failure may be the *result* of a failing circulation, as the cardiac tissues are themselves supplied with peripheral vessels. Such unorthodoxy is welcome in a perplexing subject. The diagnosis of circulatory failure should be carried out, according to Hochrein, by measuring the venous pressure instrumentally. It is curious to observe how slowly the clinical side of modern English cardiology is penetrating into Europe. Cerebral haemorrhage in young people is discussed at some length, and considered to be massive diapedesis caused by functional closure of vessels. A good deal of space is given to papers dealing with the physiology of disorders of rhythm, but no new fact emerges. One paper is devoted to a classification of the various forms of high blood pressure. A case of diverticulum of the heart with transposed viscera is described, where the electrocardiogram seems to fail to confirm the dextrocardia.

THE DUODENUM.

AN English translation has recently appeared of the volume entitled *The Duodenum*,[5] by Professor PIERRE DUVAL, Dr. JEAN CHARLES ROUX, and Dr. H. BÉCLÈRE, who for many years have collaborated in the study of this portion of the alimentary canal at the Hôpital Vaugirard, Paris. The translation is the work of Dr. E. P. QUAIN, and offers readers whose knowledge of French is limited a welcome opportunity of familiarizing themselves with the somewhat revolutionary views held by the original authors.

The French edition translated is that of 1923, but although more detailed volumes have since appeared in France, such as the two-volume work on the radiological aspects of the stomach and duodenum by the same observers, there has been no important modification of their views such as might make the present volume in any way obsolete. The most interesting part of their work is to be found in chapters ii and iii of the present volume, in which they discuss at great length the conditions described as periduodenitis and chronic duodenal ileus. In contrast to the majority of physicians especially interested in the diseases in the pyloric region, Duval, Roux, and Béclère believe that stenosing periduodenitis is not necessarily related to duodenal ulcer or to primary disease of the gall-bladder, and that it is a relatively common condition with a recognizable symptomatology. Again, they believe that an obstruction of the third part of the duodenum at the point where it crosses the pedicle of the mesentery is by no means an uncommon cause of chronic illness, and Duval has operated on many cases for the relief of these two conditions with results which are claimed to be excellent.

Surgeons and physicians in other countries have failed to confirm all the views expressed, but it is much too soon to treat them otherwise than with respectful interest, and we confidently recommend this book, with its beautiful *x*-ray photographs, to specialists not familiar with the original French literature.

ELEMENTARY PATHOLOGICAL HISTOLOGY.

IN the excellent preface to his *Elementary Pathological Histology*[6] Mr. W. G. BARNARD says, "Pathology is concerned with processes, not with states," and, later, he suggests that inflammation would be ideally illustrated by a cinematograph film. This book is, however, only a collection of single photographs and diagrams of sections from morbid states commonly met with at necropsy. The figures are attractively arranged, and are accompanied by short explanatory paragraphs and legends, in which the frequent repetition of "showing," "are shown," "are seen," etc., is aggravating and unnecessary. The expressions "a pericarditis" and "inspired food stuff" are questionable. The termination "-oma" does not mean benign, it is an abbreviation of *ογκωμα*—a swelling; "pyknotic" is derived from *πυκνος*, meaning "firm, compact." Some sentences in the paragraph on necrosis are awkwardly expressed and obscure the meaning.

Most of the illustrations are admirable, carefully chosen, and beautifully reproduced. The figures dealing with lobar pneumonia, typhoid, and tuberculosis are especially characteristic, although in Figs. 56 and 57 (high-power views of pneumonic exudation) the cell varieties are not easily distinguishable. Fig. 43 gives a good notion of purulent bronchitis, and Fig. 34 is a useful picture of organized fibrin. On the other hand, the high-power view of fibrin net and degenerated cells of diphtheritic membrane (Fig. 53) does not convey much information, and Fig. 155 is not a satisfactory representation of tubular cubical-celled carcinoma with mucous degeneration of the stroma. The note on actinomycosis and the section shown are not helpful; there is no reference to "clubs" or "rays" from which the organism receives its name.

The book should help students to recognize histological specimens and to construct the probable history of the diseased tissue.

[6] *Elementary Pathological Histology*. By W. G. Barnard. London: H. K. Lewis and Co., Ltd. 1928. (Cr. 4to, pp. 83, 175 figures on 52 plates. 7s. 6d. net.)

THE SPECIES PROBLEM.

THE first part of *The Species Problem*,[7] by Mr. G. C. ROBSON, is devoted to an exhaustive survey of those morphological or physiological attributes which differentiate species, and a discussion of the validity of such criteria as a basis for systematic grouping. This section is mainly of academic interest, but Part II includes problems which have a more distinct bearing upon medicine. Among these may be mentioned the action of a selective death rate, the modification of germ-cells by agencies such as x rays, radium, and alcohol, a review of the evidence for and against the inheritance of atrophic structure and other acquired characters, and the extent of reaction to environment. The author also discusses the relationships between structures believed to be mutually dependent during development, as, for example, primary sexual organs and secondary sex characters. The theory of "isolation" is of some interest in connexion with questions of sterility and incompatibility in mating. The term implies "any mode of separation that prevents the production of fertile offspring from the union of two distinct species"; its application is obviously limited when the human race alone is concerned. A very extensive bibliography is appended, and the text contains a wealth of data, which should make this volume a valuable source of reference.

NOTES ON BOOKS.

DR. O'DONOVAN has done good service in *Dermatological Neuroses*[8] by emphasizing the neurological factor in many dermatoses—a factor which dermatologists who are inclined to pay attention only to what they can see have usually neglected. Apart from the detection of artefacts, in which the specialty has always been skilled, there are many cutaneous conditions in which the mentality of the patient is of the greatest importance. There are others which often seem to be induced by sudden mental shock or a period of intense nervous strain. No clinician can doubt the effect of nervous strain on the physical health of the individual, but on what organ and in what way it will act no man can prophesy. It is prone to select the *locus minoris resistentiae*, and in some individuals, more perhaps than might be imagined, this is the skin. Dermatoses so produced are almost always of a pruritic character; and, vice versa, pruritus is often amenable to suggestion of one kind or another. All these matters will be found adequately dealt with in this little volume, which should be read by every practising dermatologist and physician.

The transactions of the first National Conference of the Anti-cancer Campaign in Italy[9] include an article by Professor NICEFORO, professor of statistics in the University of Naples. The article contains some timely observations on the errors of statistical interpretation. He has noticed that such errors are frequent in the interpretation of statistics of mortality from malignant disease, and that specialists in pathology and hygiene are particularly prone to them, whether they are dealing with official figures or with data collected by themselves. It is not infrequent, for example, in comparing groups in different localities or at different periods, to disregard the difference in age composition of the groups; hence there is no real basis for comparison. The author suggests a method of standardization of the rate of mortality for malignant tumours whereby this error may be eliminated. Again, a not uncommon error arises through comparing year by year the percentage of deaths from malignant disease among deaths from all causes; it is obvious that, even if the actual number of deaths from malignant disease remained the same in two consecutive years, the percentage of such deaths would vary inversely as the number of deaths from other causes varied. Many other pitfalls are discussed by the author, and his article, which is published separately, might be usefully consulted by those embarking on statistical inquiries.

The Principles of Chemistry and their Application,[10] by BARTLETT and INK, is a textbook for nurses. While it seems to be intended for adult nurses who have received no training in the elementary principles of chemistry at school, it nevertheless aims at explaining matters—such as osmotic pressure and the constitution of different sugars—which cannot be understood without an adequate foundation of learning. Although portions of the text may be read by the novice with interest and enlightenment, much of the meaning must remain obscure to all but those who have been previously instructed, and we think that the time and effort needed to digest the contents of the book would be better spent in attending an ordinary course of tuition in chemistry.

After her admirable life of her husband (reviewed in our issue of September 22nd, 1928, p. 530), Mrs. BATESON has edited *Letters from the Steppe, Written in the Years 1886–1887, by William Bateson*.[11] This expedition to the Steppes of West Central Asia was planned by Bateson in order to see the processes of evolution in action, and with two distinct objects in view: first, to find marine survivals of the Asiatic Mediterranean; but this after none months' almost exclusive search did not give any positive result; and secondly, to collect the fauna of a large number of isolated waters so as to ascertain if and how much the environmental differences produce changes in the fauna; in this, as he wrote to Sir Sidney Harmer, he was successful. The letters are interestingly written, and are illustrated by a number of extempore sketches.

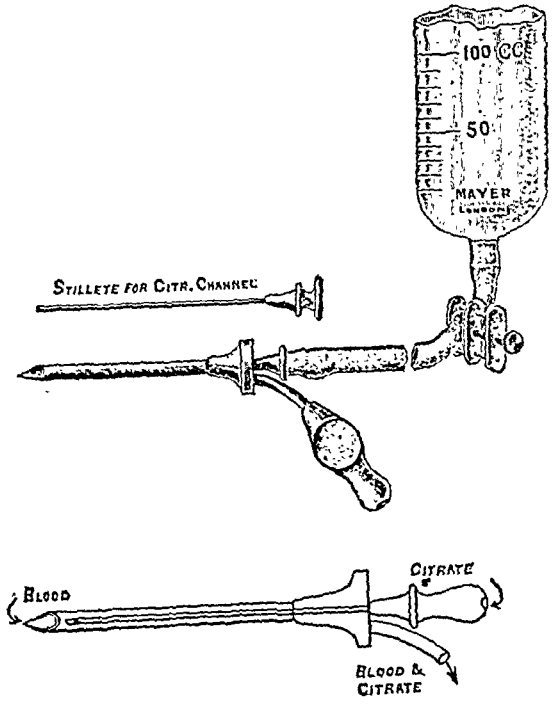
PREPARATIONS AND APPLIANCES.

A NON-CLOTTING TRANSFUSION NEEDLE.

MR. O. POPPER, F.R.C.S. (London, W.1), writes: Some years ago I experienced a little difficulty in obtaining sufficient blood from a donor, owing to repeated clotting in the needle. To overcome this on future occasions I devised the needle illustrated, and as it has been successful in other hands it may be of interest. The drawings are almost self-explanatory. There is an extra channel, of very fine bore, within the lumen of the needle, which latter is of conventional shape. Through this channel a solution of sodium citrate (2 grams in 100 c.cm.) is sent. It escapes within one-eighth of an inch of the opening of the needle, thus playing within the lumen, and is washed down the needle by the donor's blood entering at the tip. A graduated Jena flask contains the citrate solution, and is connected by rubber tubing (on which is an adjustable clamp) to the previously mentioned citrate



channel. The rate of flow of citrate from the tip of the needle can be regulated in two ways: either by raising or lowering the flask, or by adjusting the clamp and fixing the flask at a constant height of about 12 inches above the vein. The latter course dispenses with the need of an assistant. With the citrate flowing freely from the tip of the needle the latter is introduced into the vein. Blood and citrate solution escape from the barrel of the needle through the separate channel illustrated, which leads to an appropriate receptacle containing a known quantity of citrate solution. The rate of flow of citrate can be reduced once free flow has been established. The actual amount of blood withdrawn is readily estimated by adding the citrate withdrawn from the flask to that originally in the receptacle and subtracting this from the total amount of fluid in the receptacle.

The instrument is made by Messrs. Mayer and Phelps, to whom I would like to acknowledge my indebtedness.

MABEL L. CLARK, L.L.A.,
ROWETT RESEARCH INSTITUTE.

THE preliminary report, by Dr. J. B. Orr, on the result of the 1926–27 investigation into the feeding of a large number of school children was published in the *British Medical Journal*, January 28th, 1928 (p. 140).

The conclusions which might be drawn from that work appeared to the committee in charge of the test to be so interesting and important that it was decided to continue the investigation over a further period of equal length. That has been done, and the present report* deals with this period of the repeated test—namely, November, 1927, to June, 1928.

The seven centres at which the investigation was carried out were Peterhead, Aberdeen, Dundee, Edinburgh, Glasgow, Greenock, and Belfast. The number of children involved was 1,425. At each place four groups of children were selected, and each group treated differently. One group received whole milk, another separated milk, a third a biscuit ration of the caloric value of the separated milk, while a fourth acted as controls, receiving nothing.

The children of 13 to 14 years received 1 pint of milk daily.
The children of 9 to 10 years received 1 pint of milk daily.
The children of 6 to 7 years received three-quarters of a pint of milk daily.

All the milk was given at the schools under supervision. The whole milk was pasteurized, except at Peterhead and Aberdeen, where it was "certified." The separated milk was machine-skimmed.

Samples of all the milk given were taken monthly and sent to the Rowett Research Institute, where they were analysed. These analyses show that the average fat percentage of the whole milk was 3.65, and that of the separated milk 0.33.

Measurements.

The measurements were all done by one of us (M. L. C.), and were done four times everywhere, except at Belfast, where they were done three times. As in the 1927 test the children were all weighed and measured in indoor garments and without shoes. This year the heights were recorded to the nearest eighth of an inch and the weights to the nearest quarter of a pound. To obtain a fairly accurate *average* increase in weight a careful record was made at each weighing of every article of clothing worn by the child, and from these records the average weight of clothing for boy or girl was calculated. The difference between the initial (winter) and final (summer) weight of clothing was then added to the final gross weight. In Belfast, in three schools, the children were weighed in one garment only, and the difference between winter and summer weights was, therefore, the exact increase made by the child.

To obviate fluctuations as far as possible the weights and heights were taken at the same hour of the day on each occasion, this being in the case of children receiving milk before the milk was drunk. As far as possible the schools were visited in the same rotation in order that the period between initial and final weights and heights might be identical. On each visit an accurate record was obtained for each child of all absences and illnesses. Thus the exact amount of supplementary feeding was known. Any child who had missed 25 per cent. of feeds, or showed other abnormality, was excluded when calculating the results. The number so excluded was 268.

Special Conditions of the Investigation.

In considering the results of this investigation the following points should be borne in mind. The number of children involved was very large, no fewer than 1,157 being available for the measurements from which the tables are compiled. These children were divided among seven centres of population, in which the test was conducted simultaneously. Their ages ranged from 5 to 15 years, including the beginning, the middle, and the end of their ordinary school life. All the children in the six Scottish centres were living in the ordinary conditions of Scottish working-class homes, and received the ordinary diet of such homes. The milk and biscuit given to them at the schools were therefore in the nature of a *supplementary ration to their home food*. The results, consequently, must be regarded as the effect of the addition of definite quantities of milk to the average home diet of children of school age living in ordinary working-class conditions in industrial centres. It would appear to be justifiable to infer that the same results, whatever they may be, would apply to the whole school population living their ordinary life. Those conditions, from the standpoint of a nutritional investigation, are, of course, very complicated, but this test was so devised as to bring out any *significant* differences which might arise within the limits laid down.

The following three tables show the total results of the investigation.

TABLE I.—*1928—Increases: Milk versus Non-milk Groups and Percentages.*

	No. of Children.	Height Increase.	Weight Increase.
13-year Groups:			
Milk	137	1.4699 in.	5.6337 lb.
Non-milk	133	1.1908 ,,	4.2318 ,,
		=+0.2791 in.	=+1.4019 lb.
		or 23.44%	or 33.09%
9-year Groups:			
Milk	188	1.3943 in.	3.4702 lb.
Non-milk	212	1.1568 ,,	2.0695 ,,
		=+0.2375 in.	=+1.3707 lb.
		or 25.93%	or 66.88%
6-year Groups:			
Milk	242	1.5021 in.	2.5331 lb.
Non-milk	245	1.2498 ,,	1.8531 ,,
		=+0.2523 in.	=+0.6800 lb.
		or 21.16%	or 36.70%
All Age Groups:			
Milk	567	1.4585 in.	3.5775 lb.
Non-milk	590	1.1810 ,,	2.4610 ,,
		=+0.2775 in.	=+1.1165 lb.
		or 23.50%	or 45.37%
1927 increases (Scotland—all ages):			
Milk	551	1.470 in.	3.617 lb.
Non-milk	731	1.212 ,,	2.974 ,,
		=+0.258 in.	=+0.643 lb.
		or 21.29%	or 21.62%

From this table it is seen that, taking all the ages combined of the 1,157 children and dividing them into milk-fed groups and non-milk-fed groups, there is an average increase in height of 23.5 per cent., and in weight of 45.37 per cent., in favour of the milk-fed groups over the non-milk-fed groups.

It is also seen that these increases are greater in this second and repeated test than they were in the first (1927) test.

* Owing to the death of Dr. L. Cruickshank and to the absence of Dr. J. B. Orr abroad, it was decided to place the organization of the second investigation in the hands of Dr. Gerald Leighton, Medical Officer of Foods, Scottish Board of Health. This also enabled the Board's wide knowledge of the nutrition of school children and the implications of such in connexion with public health to be more readily utilized.

TABLE II.—*1928—Increases in Age Groups.*

	No. of Children.	Height Increase.	Weight Increase.
13-year Groups:			
Whole milk	68	1.4540 in.	5.5652 lb.
Separated milk	69	1.4855 ,,	5.7101 ,,
Biscuits	67	1.1194 ,,	4.4179 ,,
Controls	65	1.2633 ,,	4.0530 ,,
	270		
9-year Groups:			
Whole milk	105	1.4238 in.	3.5333 lb.
Separated milk	83	1.3569 ,,	3.2771 ,,
Biscuits	101	1.1077 ,,	2.0396 ,,
Controls	111	1.1059 ,,	2.0586 ,,
	400		
6-year Groups:			
Whole milk	121	1.5589 in.	2.7107 lb.
Separated milk	121	1.4452 ,,	2.3554 ,,
Biscuits	115	1.2424 ,,	2.1609 ,,
Controls	130	1.2375 ,,	1.5808 ,,
	487		
Total number ...	1157		

This table shows the increase in height and weight in all the age groups, with the number of children in each group. In every case the milk-fed children are ahead of the "biscuit" and "control" groups. The greatest increase in height is in the 6-year-old milk-fed group. The greatest increase in weight is in the 13-year-old separated milk group. The difference between the "biscuit" group and the "controls" is but slight, except that the 13-year-old controls did better in height but not so well in weight. In the 6-year-old group the "biscuit" group is better in weight than the "controls."

Those familiar with the manner in which statistics of this kind are worked out will be aware that, in order that the difference between two groups and figures may be regarded as "significant," that difference must be at least three times as great as the "probable error." The results in this table are calculated on that basis.

In Table III there is set forth the mean increase in pounds and inches (that is, for weight and height) in each group at each age, together with the probable error involved and the significance or otherwise of the differences.

Other Observations.

In addition to the foregoing statistical observations, two other lines were adopted which cannot be stated in figures.

Dr. C. A. Douglas examined all the children clinically when they were measured. Her report states that "in practically every case it was noted that the children receiving milk showed, even where there was obviously poor maternal care, that sleekness peculiar to a well-nourished animal. Their hair had a glossy and bright appearance. Their nails were smooth, resilient, and looked as if polished. General alertness was common to all the children fed on milk. No difference could be detected with regard to these points between the children receiving milk irrespective of the kind of milk. It was gathered from teachers and janitors that the children receiving milk were much more alert and very much more boisterous and difficult to control than the others. This latter fact was only too evident when they were waiting in small groups to be weighed."

Biscuits	(115)	v. Controls (130) ...	1.2424	,,	+0.0019	0.0221	+0.222	Insignificant.

Dr. G. W. Simpson made a different observation. He asked the headmasters to parade the children in their respective groups, he himself being unaware which group was milk-fed or otherwise. From this general survey he placed the groups in order of apparent standard of nutrition. Of five examinations thus made he found that first places of nutritional standard were accorded to three whole milk and two separated milk groups. Second places were accorded to two whole milk and three separated milk groups. Third places were accorded to all five biscuit groups, and fourth places to all five control groups. "The difference in nutrition between groups receiving milk and not receiving milk was plainly evident. No great difference was noticed between the whole milk and separated milk groups." A sixth examination did not correspond with the other five, but in this case the best nourished children had been selected as controls, while those apparently needing the milk most were put into the milk groups. The desired conditions for observation were thus not fulfilled.

A Test Reversed.

One very interesting result came out in this repeated investigation. In order to ascertain what would occur two of the previous feeding groups were reversed. A group which in the first investigation received separated milk now received biscuit. Another group which in the first investigation were "controls" now received whole milk. The general result in both cases was that they changed places, the former milk group now receiving biscuit fell to biscuit standard, while the former "control" group now receiving milk rose to the milk standard. Table IV shows the detailed results of this reversed test.

TABLE IV.—*Groups Reversed.*

Conclusions.

As the result of this repeated investigation (1927-28), it may be said at once that the tentative conclusions drawn by Dr. J. B. Orr from the first investigation were more than justified.

The great value of an additional milk ration to that already taken at home is clearly demonstrated for all ages of school children.

In the repeated test the average increase in height in the milk-fed groups in all ages combined is actually *1.21 per cent. more than in the first test.* The average increase in weight in the milk-fed groups in all ages combined is *no less than 8.75 per cent. more than in the first test.* Not only have the same milk-fed children benefited again, but they have done so to a greater extent than before. Their initial improvement has *continued over the second year.*

Once more the value of separated milk for children of school age is shown. In most groups the difference in height and weight between the whole milk and separated milk groups is not "significant," but in the six-year-old group whole milk is "significantly" better than separated for both weight and height. In every case the whole milk and separated milk groups are better than the "biscuit" or the "controls." In this repeated test the difference between the "biscuit" and the "controls" is usually "insignificant"; the effect of the extra biscuit appears almost negligible. The improvement of the milk-fed groups in general health and appearance is clearly brought out in the reports of Dr. C. A. Douglas and Dr. G. W. Simpson. Many of the teachers have recorded similar opinions.

When these results are considered, along with those published by Dr. Corry Mann in this country and those of observers in other countries, the only conclusion possible is that they have a wide public health significance, especially with the nutrition of school children.

"In 1903, when the Royal Commission on Physical Training (Scotland) issued their report, two things became clear: first, that medical examination and superintendence were essential conditions of any system of physical education; second, that in the end *the fundamental problem is one of nutrition.* . . . When every preventable ailment is prevented, and every serious disease treated to its finish, the new battalions of children coming forward have to be superintended from the nutritional standpoint." (Sir Leslie Mackenzie.) The two reports of this investigation fully substantiate these views.

Committee of Investigation.

The investigation was conducted under the direction of a committee appointed by the Scottish Board of Health with Sir Leslie Mackenzie as chairman. The members consisted of the school medical officers for the cities and towns where the work was carried out.

We desire to thank Dr. J. F. Tocher, Aberdeen, and Mr. J. S. Thomson, Rowett Research Institute, for advice and help on the statistical side of this investigation.

The results of the investigation have also been submitted from time to time to Professor A. P. Cathcart, chairman of the Nutrition Committee of the Medical Research Council.

The cost of the investigation was defrayed by a grant made by the Empire Marketing Board to the Rowett Research Institute, Aberdeen.

THE seventh issue of the *Medical and Scientific Archives of the Adelaide Hospital* contains records of various cases of general interest, and a tabulation of certain lesions found during the course of 1,000 necropsies performed between 1920 and 1925. In this survey the conditions dealt with include diseases of the vascular system, the digestive system, the female generative tract, and the ductless glands: in the *Archives* of the previous year data were given for all neoplasms. The hope is expressed that the material thus tabulated will prove of value to those engaged in research work who require references to the occurrence of peculiar lesions. Any particular case can be followed up, fuller details being obtainable on application to the registrars at the Adelaide Hospital. It is suggested that unexpected associations between various lesions may be brought out in this way, and that if similar statistics were to be made at large hospitals throughout the world, a very important mass of information would be made available.

British Medical Journal.

SATURDAY, JANUARY 5TH, 1929.

THE TEACHING OF FORENSIC MEDICINE.

IT will hardly be denied that in Great Britain, and more especially in England, we are far behind the times in the teaching and practice of forensic medicine. England and Scotland possess between them fourteen universities with faculties of medicine, besides many fully developed institutions for medical education; yet only two teachers devote themselves entirely to forensic medicine—the regius professors of this subject at Edinburgh and Glasgow. Elsewhere, even in London, forensic medicine is taught by men whose livelihood and interests are essentially in other directions, or who have retired from more active practice. In some medical schools the remuneration is so poor that the lecturer may be almost out of pocket at the end of his teaching sessions. Small wonder that in such circumstances the community has no trained body of men to call upon.

There have been many illustrations in recent years of the need for expert investigation. The general practitioner, who is frequently called upon to make *post-mortem* and other examinations in criminal cases, does not profess to know much of the subject, and is therefore disinclined to undertake this duty. The same remark applies in general to the ordinary pathologist without any special forensic training. It is true that in most cases he can ascertain the cause of death, but he is often unfamiliar both with the requirements of the authorities and with other medico-legal observations which may play a vital part in the conduct of the case. As long as those in authority in this country are content to carry on with "untrained experts" little improvement in the teaching or the standard of knowledge is to be expected. The first need is for public authorities to realize that medico-legal work of this kind requires special training, and that expert investigations are necessary, not only for the detection of crime, but often also for the protection of accused persons. With the call for experts will come an improvement in the standard of teaching. In order to give adequate instruction the teacher should be engaged in the actual practice of his subject, and have at his disposal ample material for demonstration and research. From the special nature of the subject it follows that the practical material which is needed for a teaching institute and from which expert research receives its stimulus can only come to the institute from the public authorities.

The ninth series of the valuable *Methods and Problems of Medical Education*,[1] which the Division of Medical Education of the Rockefeller Foundation started in 1924, is entirely devoted to institutes for forensic medicine. Here will be found information about the teaching of this subject in seventeen countries—namely, Austria, Canada, Cuba, Czechoslovakia, Denmark, Egypt, France, Germany, Hungary, Italy, Poland, Portugal, Rumania, Scotland, Sweden, Switzerland, and the United States of America. The articles, which are generously illustrated with plans and photographs of the laboratories and *post-mortem* rooms, appear in English, German, or French. They contain much interesting historical information, and at the same time furnish evidence of the rapid strides that this subject is making on the continent of Europe, as shown by the recent erection of medico-legal institutes. Professor Knud Sand of the University of Copenhagen traces the development of medico-legal practice from classical times, and pays a tribute to the German and French pioneers. Professor John Glaister, whose chair in Glasgow dates from 1839, describes some of the recent research work that has been carried out in his department. Forensic medicine was first taught to medical students in Great Britain in 1791 by Andrew Duncan, sen., professor of medicine at Edinburgh, and it owes much to subsequent teachers in that university, especially Sir Robert Christison, Sir Henry Littlejohn, and his son and successor in the chair, the late Harvey Littlejohn. In Poland the University of Cracow has had a chair of legal medicine since 1804, and the institute, started in 1834, has occupied new quarters since 1895. In Rumania the practice of legal medicine is said to have reached the highest degree of perfection, and the claim is made by Professor Mina Minovici that it was the first country to establish an institute, thirty-six years ago. But according to Professor Cesare Biondi the institute in Siena has been in existence for over a century, and Professor Fritz Reuter says that Austria was the first to establish an institute of legal medicine—that founded in Vienna in 1804. It seems, therefore, that the word "institute" is somewhat differently interpreted in different countries. In Turin University the Institute of Legal Medicine and Criminal Anthropology has been on its present site for just over thirty years, having previously occupied small quarters, containing Lombroso's splendid criminal collection, in a building close to the university.

The departments or institutes of legal medicine reviewed in the Rockefeller report mostly fall into two groups: those which are part of a State medical service, as in Denmark, Egypt, Rumania, and other countries, and those in which the school relies on the personality and experience of its teacher and the goodwill of the local authorities to bring cases and material to its institute. In Paris the authorities have realized the advantage and economy of a properly conducted service. The State, the city of Paris, and the university have combined to share the effort. The university supplies the expert staff, the lay staff and the establishment are under the police, and the State contributes financially. The vast resources and material of a great city are thus available for teaching and research. Other large European cities also have central institutes where, in addition to much research, a thousand or more medico-legal necropsies are performed annually. In the medical schools of this country, on the other hand, while material is available here and there through the goodwill of local authorities, the great bulk of students pass through their curriculum without any practical instruction, and post-graduate courses in forensic medicine do not exist.

The neglect of this branch of medicine in our universities and schools is much to be deplored on every ground. We have already indicated our view that progress must depend on two things—the supply of adequate material for teaching, and recognition by the lay authorities that special training and study is needed before a man is competent to undertake responsible investigations affecting the safety of the individual and of the public. From these would follow in due course the organization and supplementing of the medico-legal resources of the country. The teaching

[1] *Methods and Problems of Medical Education.* (Ninth series.) New York: The Rockefeller Foundation. 1928. (Imp. 8vo, pp. 385; illustrated.)

bodies would then be in a position to avail themselves of the assistance and co-operation of the local official expert both in the providing of material and in the practical instruction of their students. In the United States also there appears to be room for much improvement in the medico-legal service, and the need for fully equipped institutes has been plainly stated by our contemporary the *Journal of the American Medical Association*.[1] "Probably the most significant advance in this field so far in the United States is the change from the cumbersome and archaic system of coroner to the much more effective system of medical examiner, which has been made in Massachusetts, New York, and New Jersey, and which should be introduced as rapidly as possible in other States."

GROUP RESEARCH IN GENERAL PRACTICE.

"NOBODY would imagine that the use of chemistry in botany tends to make of botany a science, nor can the chemist claim to belong to the scientific side of botany. Yet laboratory subjects such as chemistry, physiology, and bacteriology are sometimes spoken of as belonging to the 'scientific' side of medicine, the implication being that the clinical side is not 'scientific.' It cannot be too strongly insisted upon that the assistance rendered by these subjects is of an elementary kind, and, though necessary, they cannot provide that knowledge which is required for the solution of medical problems. Medical science demands the carrying of investigation far beyond the reach of the laboratory worker." Sir James Mackenzie, in an article that appeared in this *Journal* on June 28th, 1924 (the last we ever published from his pen), thus differentiated medicine as a subject with aims and methods peculiar to itself, and made a plea for the scientific study of clinical problems. Much earlier than this—in October, 1919, when he founded the Institute for Clinical Research at St. Andrews—the idea of the general practitioner as an individual with his own special field of scientific work, which nobody else could quite share with him, was completely formulated in his mind. Only the general practitioner, he believed, had the opportunity of studying disease before the occurrence of pathological changes in the tissues. Whereas the specialist necessarily saw fully formed disease, the general practitioner encountered minor maladies, and illnesses revealing their presence only in the patient's symptoms. It was in the study of disease at the stage when disturbed function rather than structural change dominates the picture, in the investigation of the relation between disease and environment, in the prolonged observation of symptoms and their bearing on the future health of the patient, that Mackenzie saw the unique opportunities of the general practitioner. It was for research into these problems that the Institute was founded. How plentiful is the material demanding such investigation has been made evident by the steady stream of papers that has come from St. Andrews year by year since 1919. In the past twelve months, for example, the staff of the Institute, in co-operation with the general practitioners in the St. Andrews area, have studied "The law of disturbed reflexes" as applied to the symptoms of disease and to the reactions which occur in the skin; they have investigated the variations in temperature and pulse which are consistent with health, and the modifications which are of value in the detection of early signs of disease; they have made records of the state of the tonsils and its relation to disease. Further studies have concerned the principles of James Mackenzie as applied to ophthalmology (of which one of the fruits was a paper, "The pathogenesis of acute primary glaucoma," published in our issue of May 12th last, p. 789); the diagnosis, mode of onset, prognosis, and treatment of cardiac infection; the cytology of the blood in health and in common ill-defined diseases; and the etiology of the common cold and its relation to influenza.

Further evidence of the vitality of the Institute is afforded in its recently published ninth annual report. The organization for obtaining full and trustworthy health records of children at St. Andrews is now complete. Ante-natal histories are provided by general practitioners and filed at the Institute; notes are kept at the welfare centre of the child's health from birth to the end of the second year of life; examinations of the same children between the ages of 2 and 5 are made at the Institute at regular intervals; and observations are continued during later years. In this way over 80 per cent. of all the children born in St. Andrews are being kept under supervision. Effective correlation of the public health activities of the local authority with the work of general practitioners continues under the administration of the medical officer of health. We note also that an ante-natal clinic was established in the Institute during the year under review. The volume of routine investigations in the laboratories does not diminish, and experimental work is also in progress. As foreshadowed in these columns a year ago, the series of lectures on gastro-intestinal diseases delivered to medical practitioners at the Institute during the winter of 1927 has now been published in book form, and a review appeared on September 22nd, 1928 (p. 531). A bibliography of the medical works and articles on medical subjects written by James Mackenzie has been prepared under the direction of the council of the Institute and issued as a pamphlet.[1] It is especially pleasing to us to be reminded thus of the long succession of papers by Mackenzie which were published in the *British Medical Journal* from the year 1901 onwards, during the editorship of his staunch supporter Dawson Williams.

Most of the Institute's work, it will be noted, has involved the correlation of the efforts of a large number of practitioners. It is in some ways a paradox that James Mackenzie, himself most individual of workers, should have been so passionate an exponent of the idea of group research; that he, of all men, should have founded an Institute which has done so much to vindicate the value of team work as applied to scientific discovery. We cannot but feel that the recent inquiry conducted by the British Medical Association into the treatment of varicose ulceration, and reported upon by Dr. Arthur P. Luff in our issue of December 22nd at page 1144, would have pleased Mackenzie both in its conception and its execution. It was an investigation that provided an opportunity to the lonely practitioner, lacking even the facilities of a cottage hospital, let alone the stimulus and inspiration of an organized institute, to contribute his share to the general pool of knowledge. The Council of the James Mackenzie Institute has reason for satisfaction in the thought that the incentive to study provided by the researches and initiative of its founder continues to stimulate a new generation to expand and intensify scientific research; and that the institution he planned carries on well its other purpose of enabling general practitioners to make themselves familiar with methods of clinical research applicable in private practice.

PARLIAMENT AND MEDICAL MATTERS.

ALMOST the last thing which the House of Commons did before rising for the Christmas recess was to pass the chief medical provisions of the Local Government Bill through committee without a word of debate. The time-table of the bill had, indeed, been so arranged by the Government that these clauses were sure to be closured and put to the vote without discussion, and the Opposition, in their criticism of this time-table, did not select this point for protest. This is typical of the attitude of the House of Commons towards medical questions. While not actively hostile, it feels little interest in purely medical matters, and shows no desire to discuss them. When the Ministry of Health Estimates have come under discussion during the year the Opposition chose to debate them in order to talk about Poor Law administration and the relief of the unemployed and their families. Only late at night were medical members able to interpose speeches about public health, and these were treated as unwarrantable intrusions. The subsequent speakers returned abruptly to non-medical topics, and the final reply from the Government was concerned only with the latter. Somewhat similarly, the parliamentary consideration earlier in the year of the National Health Insurance Bill was concentrated most upon the proposals for preventing the unemployed from lapsing from benefit. Labour members proposed to add extensively to the additional medical benefits which might be paid by approved societies having accrued surpluses. These proposals, in several cases, were admittedly made as a counsel of perfection and in the knowledge that within the financial limits of the national health insurance scheme no society could provide the suggested benefits. On the other hand, certain Labour members denounced the theory that additional benefits should be expended on medical and cognate services, and enunciated the doctrine that the first need and right of an insured person, when a society had a surplus, was to increases of cash benefits. On the Labour benches the belief still lingers that the national health insurance scheme should be in part a sharing-out benefit club for providing occasional financial windfalls to wage-earners. Though medical and health subjects have been little debated in either House during 1928 —the only adequate debates, indeed, being in the House of Lords upon the Preservation of Infant Life Bill—no anti-medical bias has been shown. Members simply care little for health questions, and, with a general election approaching, do not see how any votes can be won on them. A few questions about "artificial sunlight" treatment in schools and under public authorities are almost the only medical inquiries which laymen on the back benches have put to the Government. The former flood of questions about the medical treatment and classification of ex-service men has almost ceased now that the Ministry of Pensions has applied the seven years limit to claims. Attention has been directed to the closing of hospitals by the Ministry, and Dr. Fremantle has suggested that special buildings and expert staffs might be taken over by civilian authorities. Fewer questions have been put concerning small-pox and vaccination since the report of the Royal Commission. The year 1928 saw one parliamentary session ended at the beginning of August and another well advanced at the end of December as a result of a new arrangement of the annual business of Parliament. In the first session the chief measure of medical importance was the National Health Insurance Act, which received the Royal Assent on July 2nd and came into force this week. Financial and tactical considerations prevented Mr. Chamberlain from incorporating in it all the proposals of the Royal Commission on National Health Insurance, but its provisions are consistent with the recommendations of that body. During the discussion of the measure in standing committee medical members of Parliament made effective contributions to the debate. The Registration (Births, Deaths, and Marriages) Bill, introduced by a private member with the concurrence of the Ministry of Health, passed the House of Commons but did not secure the Royal Assent. Its substance has now been incorporated in the Local Government Bill. Less direct medical interest attaches to the Shops (Hours of Closing) Act, the Slaughter of Animals (Scotland) Act, and the Rag Flock (Amendment) Act, all of which became law on August 3rd. The Representation of the People Act, passed in July, confers the parliamentary and municipal franchises on women at and above the age of 21 on the same terms as men, but does not otherwise affect the university franchise, although Opposition speakers urged its abolition. The Budget was noteworthy for the imposition of a tax on motor fuel—but not on lamp kerosene—for the purpose of financing the Government scheme for the relief of rates on industrial property. During the session the Government set up a committee to inquire into the causes of maternal mortality, and another to inquire into the training of midwives. In the session 1928–29, the last of the present Parliament, the House of Commons has so far passed more than fifty clauses of the Local Government Bill through committee, and the Lords have amended the Preservation of Infant Life Bill so as to safeguard more fully the doctor or nurse in bona fide attendance at a lying-in. The Government has secured sanction for a special grant to relieve destitution among women and children in the coal-fields. The Parliamentary Medical Committee has met regularly during the year, and has had useful conferences with representatives of the British Medical Association. Its members have made many sound speeches in the House, but when, as on the National Health Insurance Bill and the Local Government Bill, medical questions become party issues, the members of the committee generally keep in step with their parties, and not with one another.

THE CAIRO MEDICAL CONGRESS.

AN International Congress of Tropical Medicine and Hygiene was held at Cairo from December 15th to 22nd on the occasion of the centenary of the faculty of medicine and the Kasr-el-Aini Hospital. At the official inauguration of the congress on the morning of December 15th, in the presence of His Majesty King Fuad I, an address of welcome to the delegates was delivered by His Excellency Dr. Mohammed Shahin Pacha, Under Secretary of State for Public Health. Sir George Newman, chief of the British delegation, in his reply, expressed the hope that the congress would help to foster international co-operation in the study of disease, especially in relation to the problems of prevention. Sir Robert Philip, the official delegate of the British Medical Association, presented an address to the faculty of medicine congratulating it in the name of his 34,500 fellow members on having attained its centenary. The address, which was signed by Sir Ewen Maclean, President of the Association, and Dr. H. B. Brackenbury, Chairman of Council, recalled with pleasure the active part which members of the British medical profession had taken in the work and development of the faculty, and expressed the hope that the international congress to be held in connexion with the centenary celebrations would prove fruitful, not only in illustrating the advances that had been made during the last century, but in clearing the path for continued progress. On December 16th King Fuad laid the foundation stone of the new Kasr-el-Aini Hospital and medical school, erected at Roda Island to take the place of the old buildings. The new hospital will accommodate 1,500 in-patients. During the same afternoon Sir Berkeley Moynihan conferred the honorary Fellowship of the Royal College of Surgeons of England on Dr. Ali Bey Ibrahim, university professor of surgery. The various scientific

sections of the congress met daily from December 17th to 21st, two general meetings being held to discuss ankylostomiasis and bilharziasis respectively in all their aspects. Among those who made communications were Sir StClair Thomson, Sir William de Courcy Wheeler, Professor Munro Kerr, Dr. J. B. Christopherson, and Sir Frank Colyer. Sir William Wheeler was present with Sir Robert Philip as official representative of the British Medical Association. At the final meeting of the congress the honorary degree of Master of Surgery was conferred on Sir Berkeley Moynihan, Sir Holburt Waring, and Sir William Wheeler; and that of Doctor of Medicine on Sir Robert Philip, Sir Cooper Perry, and Professor G. H. F. Nuttall. Several important decisions were reached at this meeting. It was resolved to hold the next congress in Holland in 1931; a plea was made for the study of physical anthropology by faculties and schools of medicine in tropical countries; and a resolution was adopted to invite the Governments of all nations represented at the congress to co-operate to combat leprosy by improving the facilities for diagnosis, ambulatory treatment, isolation, and inspection of patients' relatives and contacts.

ASTHMA RESEARCH.

CONSIDERABLE progress has been made by the Asthma Research Council since we noted on March 17th last (p. 458) the preliminary steps that had then been taken to organize a massed attack upon the problem of asthma. Special research clinics are being established in eight hospitals; they will be financed by the council, but the work will be arranged and supervised by members of the local staffs. These hospitals are: Guy's, where Drs. H. W. Barber, R. D. Gillespie, and A. F. Hurst will be in charge of the clinic; the Royal Infirmary, Liverpool, under Professor John Hay; the Royal Infirmary, Edinburgh, under Dr. Cranston Low; the Stobhill Hospital, Glasgow, under Dr. James Adam; the Birmingham General Hospital, under Professor H. W. Wynn; the Royal Victoria Hospital, Belfast, under Sir Thomas Houston; the Royal Infirmary, Manchester, under Dr. F. E. Tylecote; and the Hospital for Sick Children, Great Ormond Street, under Dr. E. A. Cockayne. The question of providing facilities for such clinics is also being considered by the Brompton Hospital and the Bristol Royal Infirmary. The Leeds General Hospital, while not in a position to do this, has suggested a different scheme of co-operation. The laboratories of the Rockefeller Institute at the Edinburgh Royal Infirmary and of the University of Bristol will be utilized for research work, under the direction of Professor Murray Lyon and Dr. Cranston Low at Edinburgh and of Professor J. A. Nixon at Bristol. Moreover, the laboratories at King's College Hospital and St. Mary's Hospital, London, have arranged to work in conjunction with the medical advisory committee of the Council, while the Edinburgh Asthma Inquiry Committee and the Glasgow Asthma Investigation Committee will also co-operate. The British Humane Association having provided a grant of money for the investigation of special physico-therapy methods in use at Continental spas, Dr. Una Ledingham was enabled to visit Reichenhall, Mont Dore, Ems, Hamburg, Berlin, and Paris, and examine such procedures as saline and pine oil inhalations, automatic breathing apparatus, nasal gas applications, ultra-violet light therapy, and diathermy. The Medical Research Council has made a grant to Dr. G. H. Oriel for the continuation of his research at Guy's Hospital into the biochemical causation and treatment of asthma. From the Halley Stewart trust endowment a grant of £2,500, spread over four years, is forthcoming; part of this money is being devoted to the establishment of a clinic at Great Ormond Street Hospital for the study of asthma in children, under the direction of Dr. Cockayne, and the remainder to the provision of a clinic at Guy's Hospital to supplement and complete Dr. Oriel's research, using the methods of nasal treatment advocated by Dr. Haseltine of Chicago for other patients, who will thus serve as control cases. A form for the collection of asthmatic family histories and statistics has been prepared by the Asthma Research Council for circulation, with a view to tracing hereditary influences affecting the onset of asthma and its relationship with other syndromes. It is hoped that medical practitioners will encourage asthma patients to complete these forms in order that scientific data may become available for study. We publish elsewhere (at page 43) a letter from the secretary of the Asthma Research Council calling attention to a meeting at the Mansion House on January 15th, which it is hoped that many doctors will be able to attend. The Medical Advisory Committee has been enlarged, and now includes: Dr. A. F. Hurst (chairman); Professor R. J. S. McDowall (vice-chairman); Dr. James Adam, Dr. L. S. T. Burrell, Dr. Cockayne, Dr. John Freeman, Dr. Gillespie, Dr. Barber, Professor Hay, Sir Thomas Houston, Dr. W. E. Hume, Dr. Cranston Low, Mr. V. E. Negus, Professor Nixon, Dr. S. Gilbert Scott, Dr. Tylecote, Dr. G. W. Watson, and Professor Wynn.

SEASONABLE WEATHER.

ARE there any grounds for the popular belief that Christmas weather is milder than it used to be? The idea contains no inherent improbability, for nothing in the English weather is constant except change, nothing predictable except the passage of the seasons—"If winter comes can spring be far behind?" The old-fashioned Christmas, the Christmas of bright sunshine, cold crisp air, and a snow-decked countryside, may be a myth invented by Victorian novelists and fostered by the notoriously unreliable memories of people as they get on in years. The phenomenon of pseudo-memory is, after all, well known to psychologists. Through the haze that envelops our earliest years a single snowy Christmas may proliferate an uninterrupted series in the memory; Christmas cards are forgotten, but the images painted on them may be projected on to the outer world. The impulse to idealize the past, moreover, is one from which very few of us are exempt. The mind, regressing from the problems of the present, finds some compensation in a fantasy of past perfection. Perhaps it is this tendency that underlies the question, "Mais où sont les neiges d'antan?" Dr. C. E. P. Brooks, in an article published in *Nature* on December 22nd, suggests much the same idea. "A few frolics in the snow when we were young," he writes, "would colour all our memories of winter. The change may not be in the weather, but in ourselves." Virginia Woolf, on the other hand, seems to subscribe to the theory of a changed climate, of a climate that has lost its rigors, but at the same time shed much of its attractiveness. In that puzzling book *Orlando* she informs us gravely that the frost in Elizabethan times was so severe "that a kind of petrifaction sometimes ensued; and it was commonly supposed that the great increase of rocks in some parts of Derbyshire was due to no eruption, for there was none, but to the solidification of unfortunate wayfarers who had been turned literally to stone where they stood. . . . Frozen roses fell in showers when the Queen and her ladies walked abroad." In the eighteenth century there was snow, and the air was dry; but in the nineteenth century Orlando became aware that a change had come over the climate of England. "Rain fell frequently, but only in fitful gusts, which were no sooner over than they began again. The sun shone, of course, but it was so girt about with clouds, and the air was so saturated

with water, that its beams were discoloured. . . . A change of diet became essential. The muffin was invented and the crumpet. Coffee supplanted the after-dinner port, and as coffee led to a drawing-room in which to drink it, the home . . . was completely altered." Thus, Virginia Woolf tells us—and she does not flicker an eyelid—"stealthily and imperceptibly, none marking the exact day or hour of the change, the constitution of England was altered and nobody knew it." The writings of Henry Thomas Buckle have indeed accustomed us to the idea that at any historical epoch the prevailing meteorological conditions may serve in large measure to explain the character and the social, political, and economic life of a people. Such a climatic conception of history finds ready acceptance among the English people, who from day to day observe the profound influence of climatic and weather conditions upon their psychological make-up and their physical activities. The adventurous spirit of our race may thus have been no spontaneous emergence of national character; it may have been bred of an urgent desire to escape from the English climate. According to this line of thought the British Empire was built up by a people made hardy and adaptable by our climate, but none the less goaded to travel by a deep yearning for settled weather. One is reminded of the charming Persian Ambassador cited by Morier, who, asked by his hostess at an English party if it was true that in his country people worshipped the sun, replied, "Yes, madam; and so would you in this country also, if you ever saw the sun." Here, indeed, was a belief founded on a sketchy impression. Is the popular notion that weather conditions have changed established on any securer basis? Dr. Brooks thinks it is. "During the past century," he writes, "winters have become steadily warmer, and the average of the past ten years, 41.1° F., is the highest since records began. . . . There appears to have been a real change of climate about 1750. . . . This was the time of the great 'frost fairs' on the Thames, notably 1683–84, 1715–16, and 1739–40. . . . If the old-fashioned Christmas ever had a real existence no series of years is more likely to have given birth to the tradition." Surely Dr. Brooks has forgotten the Christmas of 1927.

OSLER AS EPIDEMIOLOGIST.

IN amplification of remarks made at the meeting of the Osler Club last July, to which we alluded on July 21st, 1928 (p. 117), Dr. J. D. Rolleston, in a recent article,[1] emphasizes the keen interest taken by Sir William Osler in the study of epidemic diseases, an interest doubtless inspired to some extent by the fascinating history connected with many of them. Osler's familiarity with the work of the early epidemiologists is illustrated in his textbook and his miscellaneous writings, particularly the essay on "Some aspects of American bibliography." Although small-pox, cerebro-spinal fever, and venereal disease formed the subject of some of his more important addresses, typhoid fever and tuberculosis were the infectious diseases to which he devoted most of his attention. The importance he attributed to typhoid fever—which, owing to the heavy toll it exacted of young persons, he called the "Minotaur of infectious diseases"—is shown not only by its occupying the first place in his textbook, but also by his dictum that a student could learn most of medicine and a good deal of surgery—the latter much at the patient's expense—by a study of this disease alone. The insanitary conditions responsible for the outbreaks of typhoid fever—which was rife in America, particularly at Baltimore, when Osler was professor of medicine at Harvard, frequently provoked a protest from him. The incidence of typhoid fever, he maintained, was the sanitary index of the community, and in the matter of purification of their large towns he accused the United States as being a generation behind Europe. Many years later, shortly after the outbreak of the war, he urged the necessity of antityphoid inoculation, and denounced the "sons of Belial" who had been trying to oppose the measure. In like manner his conviction of the value of vaccination against small-pox is illustrated in a characteristic passage in the essay entitled "Man's redemption of man," in which he issues a "Mount Carmel-like challenge to any ten unvaccinated priests of Baal." Osler's interest in tuberculosis assumed a very practical form. In 1902 he was responsible for the establishment of the first tuberculosis dispensary at Baltimore. He also took an active part in the campaign against tuberculosis in Philadelphia, and later in England, where he helped to form the National Association for Prevention of Consumption in 1903, and started an Oxford branch in 1910; it was only his fatal illness which prevented him from delivering an address before the association in 1919. Osler's interest in epidemic disease was maintained until the end. In June, 1918, he paid a special visit to the London Hospital to see the first cases of lethargic encephalitis, and a few months before his death he approached the Foreign Office for concerted medical action to deal with the deplorable sanitary conditions in Vienna, which were a menace to public health, not only in Germany and Austria, but also in the rest of Europe. In conclusion, Dr. Rolleston gives a short account of Osler's views on the alcohol problem.

[1] *Clinical Journal*, November 28th, 1928, p. 573.

THE FIELD OF BACTERIOLOGY.

THE world of microscopic creatures is being explored from many different points of departure by investigators with widely different scientific interests. The medical bacteriologist has, as his primary motive, the study of bacteria in relation to human disease, and he is comparatively uninterested in non-pathogenic germs. Urged by the pressing claims of health and disease, research work on the small group of pathogenic bacteria has made more progress than work undertaken for scientific interest alone, and to-day we find that the disease-producing microbes are more accurately described and their habits much better known than is the case with the harmless germs of water and the soil. The success which has attended the search for the cause of infectious disease, and the new means of prevention disclosed by these scientific triumphs, though they have proved of incalculable benefit to mankind, should not be allowed to eclipse the advantages to human welfare gained by progress in other branches of bacteriology. The preservation of food, the making of butter and cheese, the canning of meat, and the bottling of fruit—all these are carried out with more efficiency and security to-day because the work of microscopic allies and enemies is better understood in the industries concerned. Mankind has reaped advantages from progress made in the exploration of the microscopic world from whatever direction it has been undertaken, whether the starting point has been the bacteriology of water, of the soil, of milk, of vinegar, or alcoholic beverages. The time has now come when the medical bacteriologist cannot maintain a just perspective unless he knows something of the knowledge gained by non-medical investigations of bacteriological problems. Hitherto the attainment of this knowledge has not been an easy matter, for he cannot be expected to study textbooks written for farmers, dairy workers, bakers, and brewers, and there have not been many books which have attempted to interpret the science of bacteriology from a non-professional point of view. A book has recently been published, entitled *The Newer Knowledge of Bacteriology and Immunology*,[1] which serves a useful purpose in

[1] *The Newer Knowledge of Bacteriology and Immunology.* Edited by Edwin O. Jordan and I. S. Falk. Chicago: University of Chicago Press; London: Cambridge University Press. 1928. (Roy. 8vo, pp. x + 1,196; illustrated. 50s. net.)

correlating bacteriological problems. It has the outward appearances of a massive dictionary, its 1,196 pages being stoutly bound together in one volume. Eighty-two contributors have written on the particular branches of bacteriology of which they have special knowledge, and the book is edited by Drs. Jordan and Falk of the University of Chicago.

COCKTAILS AND THEIR EFFECTS.

THE practice of cocktail drinking appears to be almost as prevalent in medical circles as in other society gatherings, and might therefore be supposed to have been condoned rather than condemned by the profession. We have, indeed, heard the custom defended by one grave authority on the plea that it was a stimulant to the endocrine system. In the current issue of the *British Journal of Inebriety* Professor W. E. Dixon of Cambridge describes the composition and effects of this American importation, which has largely taken the place of sherry and bitters or gin and bitters as an *apéritif* before meals. The cocktail usually consists of a solution of volatile oil, more rarely bitters, with vermouth and spirits, such as gin, whisky, or brandy. The most important constituent in each case is alcohol, the oils serving mainly as a mild irritant to the stomach. The spirit is very rapidly absorbed from the empty stomach, and the rate of absorption is still further facilitated by the irritant action of the oils. Having reached the blood it is absorbed into the tissues, and especially the central nervous system, where it produces a stimulation of the nerve cells which continues until the tension of alcohol in the nerve cells and blood becomes equal, after which the alcohol exerts its ordinary action on the central nervous system. The action of the cocktail, unlike that of ordinary alcoholic beverages, is immediate, but its duration is transient, being limited to fifteen or twenty minutes at the most. This form of drinking, Professor Dixon maintains, is particularly pernicious for young people of either sex, who form a large percentage of cocktail drinkers, partly to lose their shyness and partly in a spirit of bravado. Not only does it impair their stomach, but it helps to promote the habit of excessive drinking more than any other type of beverage.

THE late Mr. J. H. Plummer of Southport has made a munificent bequest to the University of Cambridge for the endowment of two chairs for the promotion of modern scientific research. Almost the whole of his estate, valued at more than £250,000, is bequeathed to the University in the form of a trust to be known as the John Humphrey Plummer Foundation.

THE KING'S ILLNESS.

THE communiqué printed below has been authorized for publication in the *Lancet* and the *British Medical Journal*. It supplements the reports published on December 15th and 22nd, and is dated Wednesday evening, January 2nd. We believe that our readers generally will approve this policy of telling the public as much as possible, through the most appropriate channel, about the illness of their King.

"For true understanding of the position it must be emphasized that neither in its inception nor in its subsequent course has this illness conformed to what is called 'pleuro-pneumonia'; rather was it a streptococcal septicaemia which by fortunate happening localized at the base of the right lung, first imperfectly and later as an empyema ('fixation abscess') forming between the base of the lung and the diaphragm. In the second phase of the illness (vide report December 22nd) the clinical picture—dusky appearance, dry cracked tongue, delirium, subsultus, exhaustion—was that of a severe toxaemia, and resembled that of a case of severe typhoid fever in the third or fourth week. So now the picture is that of the aftermath of a severe general infection. The empyema wound is now clean and steadily diminishing in size, the discharge from the pleural cavity is small in amount, and the streptococcus grown from the pus (identical with that originally found in the blood) is diminishing in potency. Eusol has been an effective local application, and though—through the courtesy of an American colleague, Dr. Sherman of Pittsburg—a supply of Dakin's solution, electrolytically prepared, has been recently received, there has been no opportunity to use it because the necessity for any such local application has passed.

"On the other hand, the disinclination for food and the dryness of the tongue, the low blood pressure, the weakness and wasting, the notable exhaustion, though slowly improving, will for long be an anxious problem. It will be readily understood that while this exhaustion state is pronounced, the margin of reserve power must be narrow, and that small set-backs, inevitable at this stage, have a correspondingly more severe effect. It is important that the public should not interpret such set-backs or reports of 'no change' as relapses. During each week there will be ups and downs, and progress will consist of a slow and increasing predominance of the ups over the downs. One of the inevitable difficulties in so long an illness is to convey to the public a true picture—neither too bright nor too dark. It is for this reason amongst others that the courtesy of the medical press is valuable, in order to convey through their readers to the public fuller information, and so avoid the risk of misunderstanding.

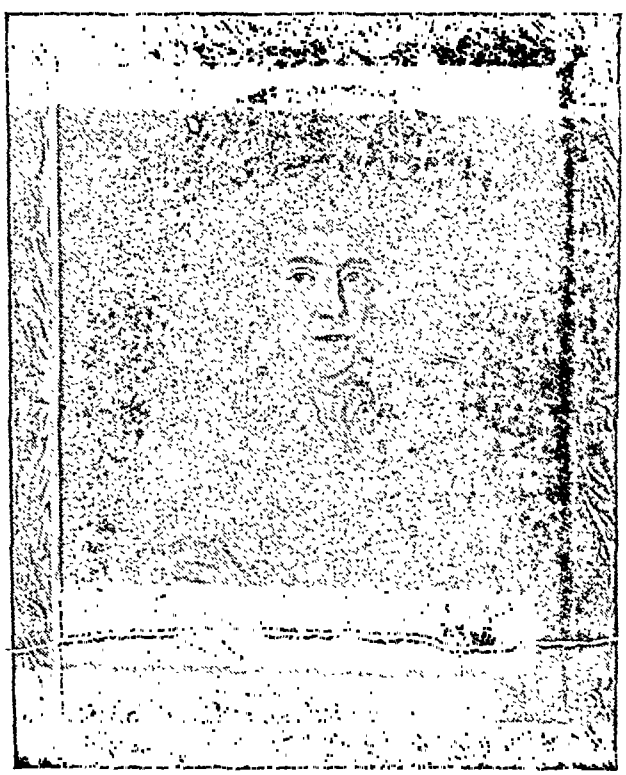
"As regards nourishment, about which so many suggestions have been received, the difficulties will be understood when it is stated that there is disinclination for most foods and dislike for many, and that weakness necessitates that nourishment be given by a nurse with a feeder. Adequacy of nutriment, both as regards quantity and variety, is now being secured, though not without difficulty. Moreover, the combating of loss of weight, which has been notable, depends not only on food taken but food digested and assimilated, and here again the exhaustion tells its tale. The blood pressure has fallen too low and the calcium content of the blood has of late considerably decreased. The administration of calcium, parathyroid extract, and strychnine is apparently beneficial. The same is true of ray therapy, which is being continued. It need hardly be stated that the question of blood transfusion has received full consideration. In an illness of this complicated character the indications for transfusion must be clear, and it must be remembered that with the most skilled procedure its employment would in this case entail risk. The striking results following transfusion—for example, in cases of anaemia due to either haemorrhage or infection—are apt to lead to its employment in other conditions without adequate consideration of the pros and cons. It is sufficient to repeat that in this grave illness it has been fully considered, and put aside at the present stage as definitely undesirable. Moreover, the red blood cell count is one of the most hopeful features, for whereas in the early days of the illness the red count was as low as 2,900,000, to-day it reaches 4,300,000.

"The exhaustion is as much a weariness of mind as of body. Though there is an increasing sense of the burden of his illness, the will of the King to live is there. Because of this exhaustion the course must be long and for the present anxious. None the less, improvement and progress are taking place slowly but surely enough to justify the hope that the King will be restored to his people."

Nova et Vetera.

JOHN MAPLETOFT, 1631–1720.

JOHN MAPLETOFT, to whom Sydenham dedicated the third edition of his *Medical Observations*, was the son of the Rev. Joshua Mapletoft, vicar of [illegible] Essex, and the godson and great-nephew of [illegible] jun., of Little Gidding. He was born at Margaretting in 1631, and in 1635, when he was 4 years old, his father died. Thereupon his godfather, Nicholas Ferrar, took charge of him and brought him up in the devout family community which he (Ferrar) had founded there. John Mapletoft was educated at Westminster under Dr. Busby; here he met John Locke, and formed a friendship with him that lasted all through their lives. He was originally intended for Holy orders, but the troublous times of the Civil War postponed the fulfilment of his desire. In 1648 he went from Westminster to Trinity College, Cambridge, took



John Mapletoft.

his B.A. degree in 1651, became a Fellow of his college in 1653, and in 1654 was incorporated B.A. at Oxford. He was expelled from his Fellowship by the Parliamentary Visitors, and, with many other graduates of Cambridge who were forced to leave Cambridge for their loyalty, retired to Oxford. Possibly he took this step for the reason given by Anthony Wood, "to avoid the cruelties and barbarities of the presbyterians." But Wood mentions another reason in his *Fasti Oxonienses* (under the year 1655), where he says that many of the graduates by incorporation came to Oxford "for the sake of the public library." In the case of Mapletoft the cause is not clear, because in 1655 he proceeded to the M.A. degree at Cambridge.

For three years (1658–1660) he travelled as tutor to Joscelyn, son of Algernon, last Earl of Northumberland. After 1660 he studied medicine in Italy, and, having been restored to his Fellowship, took his M.D. degree at Cambridge. Then he practised in London, where he made the acquaintance of many eminent physicians—Willis, Cox, and Sydenham—continuing there his close friendship with Locke. An interesting event occurred at Oxford in 1669.

"This year," to quote Anthony Wood again, "Sheldon's Theatre being opened, and dedicated for a learned use was a most splendid Act celebrated therein on the 12th of July and very many Cambridge men coming to the solemnity . . . were incorporated in a Congregation held in the House of Convocation the next day."

Among the Cambridge men thus honoured was John Mapletoft, described by Wood as "afterwards Professor of Physic in Gresham College and Fellow of the Royal Society." His first lecture as Gresham Professor was delivered in 1675. Unlike his friend Sydenham, who makes no mention of the work of Harvey, Mapletoft devotes considerable attention to this work.

"I will begin," he says, "with that celebrated and useful discovery which was first made and published to the learned world by that ornament of his own age and of this nation to all ages, the judicious Dr. Harvey concerning the motion of the heart, and circulation of the blood."

His admiration for Harvey did not end with mere words of eulogy; Mapletoft presented to the Royal Society that well-known portrait of Harvey in a skull cap which hangs in the rooms of the Royal Society at Burlington House.

When he resigned the Gresham Professorship in October, 1679, Mapletoft retired from the practice of medicine, an occasion which caused John Locke to write regretfully to him: "I like our calling the worse since you have quitted

Rebecca Mapletoft (*née* Knightley).

it." In November, 1679, at the age of 48, he married Rebecca, daughter of Lucas Knightley of Hackney, a Hamburg merchant, and lived in the country to prepare himself quietly for Holy orders. He was ordained deacon and priest in 1682, and became rector of Braybrooke in Northamptonshire soon after. In 1684 he was appointed vicar of St. Lawrence Jewry. In 1689 this remarkable man, who had seen Charles I visit Little Gidding in 1642, and again in his flight for safety in 1646, had the degree of D.D. conferred upon him when King William went to Cambridge. His ministry was no mere leisured evening to his life, for he was one of the active promoters and founders of the Society for the Propagation of the Gospel in Foreign Parts, a member of the Society for the Promotion of Christian Knowledge, president of Sion College, and a director of Greenwich Hospital. In 1710, after a serious illness, John Mapletoft resigned his living, and spent his last years in the house of his daughter and her husband, Dr. Gastrell, Bishop of Chester. There he enjoyed a soft and gentle old age, preserving to the last a gaiety and cheerfulness of temper, seeming always desirous to gain the affections of those about him that he might engage them to virtue and religion. He clung affectionately to the recollections of his early life in the family community of the Ferrars, giving to his son a Gidding Concordance, in which he wrote: "I desire that it may be preserved in his family as long as

may be." His long life covered an era in English history full of strife and change, yet such was the largeness of his heart that he could number among his friends Sydenham, who was one of Cromwell's captains, and Locke, whose father had been a captain in the Parliamentarian forces. He died in 1721, and was buried under the altar in St. Lawrence Jewry.

The portraits of John Mapletoft and his wife which illustrate this article are by John Riley, a well-known Court painter, whose fame has been depressed by his best works having been ascribed to Lely. Charles II, James II and his queen, and William and Mary all sat to him. We have been enabled to publish photographs of these portraits by the kindness of one of his descendants, Mr. A. J. Leonard of Bristol.

The portraits are at present in possession of Mr. J. Burford Leonard of 7, Hughenden Avenue, Belfast, who has had them photographed, and has generously sent prints for reproduction in the *Journal*. One of John Mapletoft's daughters married the Rev. Edward Burford, in whose family the portraits have been handed down as heirlooms, and have thus become the highly prized inheritance of Mr. Burford Leonard.

J. A. NIXON.

SOCIETY OF APOTHECARIES OF LONDON.

APPEAL FOR HALL RESTORATION FUND.

AN appeal has been issued by the Court of Assistants of the Society of Apothecaries of London to its licentiates in all parts of the world for contributions towards the restoration of its ancient hall in Water Lane, Blackfriars. It was found some months ago that the fabric was in danger of collapse owing to damage caused by the death-watch beetle in the main timbers, and it has therefore been necessary to make immediate provision for reparation and preservation. The work necessary has been extensive, and the cost, which it is estimated will exceed £20,000, has caused grave concern to the Court, which accordingly decided to ask those most intimately associated with the Society to assist. Great care has been taken to preserve the ancient character of the building and to retain the features which give the Hall its peculiar historic interest.

The building, it may be recalled, was erected in 1671 on the site occupied by the former home of the company, which had been burnt down five years earlier in the Great Fire of London. Its situation in the City itself, and the nomenclature employed in its administration—governed as it is by a master and wardens, with a court of assistants—remind us that the Apothecaries' Society of London is one of the old City Guilds, with an independent charter granted in 1617 by James I. The appeal for support in the restoration of the Hall is, therefore, made on two grounds—the desirability of preserving a monument of historic interest, and the duty of maintaining unchanged that which is associated with so much of significance in the history of the profession of medicine. On both grounds the request for financial aid seems to merit the support of the profession at large, while among those for whom the Hall of the Society of Apothecaries was the portal through which they entered our profession the appeal should be difficult to resist.

The following list shows donations to the restoration fund received up to December 19th, the total being £639.

First List of Donations.

£100.—H. H. Clarke.
£52 10s.—Sir William Wells and Alfred Hepburn.
£25 5s.—Colonel E. C. Freeman.
£21.—W. Adams Frost.
£21.—J. Bright Banister and Mrs. Courtauld.
£15 15s.—R. Erskine Gray, P. Traer Harris, Herbert R. Mosse, and T. D. Paradise.
£10 10s.—Thomas Wakefield, Cecil Wall, Algernon Brenchley, F. de Havilland Hall, Sir George Makins, Victor S. Partridge, and Sir Hugh Beevor.
£5 5s.—Horace Sworder, Sir George S. Buchanan, J. O. W. Barratt, H. J. Hett, R. W. Statham, Samuel Osborn, Lieut.-Colonel C. T. Samman, R. Austin Freeman, A. H. N. Lewers, John H. Chambers, Edmund Johnstone, Miss Mary Rathbone, R. H. Hayes, Sir Ronald Ross, and A. P. Gibbons.
£3 3s.—Peyton Beale, E. Treacher Collins, Frank P. Haviland, and William Handcock.
£2 2s.—James Brierley, D. Cotes-Preedy, L. V. Cargill, J. W. Carr, J. Fletcher Horne, Miss Katherine Heanley, Andrew Boutflower, Edmund Couchin, D. Colquhoun, A. P. Luff, Evan H. Hare, J. Müller, Louis Savatard, and Norman W. Rawlings.
£1 1s.—T. B. F. Eminson.
£1 1s.—Miss V. E. M. Bennett, T. M. Beattie, M. G. Biggs, Hobart J. W. Barlee, G. H. Bate, C. Bradford, A. C. Barrow, R. H. Birtwell, John Bate, Bertram Bond, S. H. Appleford, W. B. S. Relton, V. Ray Smith, H. Skelding, James B. Couche, R. H. Chadwick, George Aldridge, F. W. Cock, E. Vipont Browne, W. H. Brazil, H. J. Clutterbuck, Valentine Blake, Thomas S. Byass, Herbert L. Dowsing, James Ewing, J. Cooper, Alfred Duckworth, J. Coxhead Cook, Herbert A. Browning, W. E. K. Kirby, Eric Evans, J. Scott Challice, E. F. Hoare, Richard Hickman, F. H. Beattie, A. J. Dowck, Austin Fenniss, A. G. Everard, T. M. Angior, J. P. Llewellyn, E. Spencer Evans, W. Dunstan, W. H. Harsant, A. L. Joscelyne, E. E. Bowden, E. S. Killick, Miss Kathleen Dawson, Michael Bulman, James Harrison, Miss Laura G. Rees, G. Aubrey Jelly, G. E. J. Crallan, J. C. M. Given, G. Sydney Green, J. E. Elam, Francis Lowe, N. Pines, W. Eric Farnham, Arthur Lowndes, J. W. Papillon, Hugh S. Jeffries, H. F. M. Pope, E. L. Payne, S. R. T. Griffith, A. D. Owen, John W. Meek, J. Wallis B. Mason, H. Gilbert Nicholson, John Kendall, J. H. Lightbody, Miss Ada M. Browne, G. Foster Smith, S. B. S. Smith, M. Melglare, W. G. Sargent, James Miller, L. Maybury, and Edwin G. Firth.
10s. 6d.—T. W. Graves.

ROYAL MEDICAL BENEVOLENT FUND.

DURING the year 1928 the Fund has voted no fewer than 457 grants, amounting to £8,621.

The fact that the work of the Fund has greatly increased, and that the appeals for help are more numerous than ever, will be realized by comparing the above figure with that of the preceding year. The sum voted is £1,456 over that for 1927. Annuities amounting to £4,970 have been given to 185 persons. The average amount of the annuities is £40 per annum, but owing to a recent legacy the Fund has been able to grant six annuities of £100 each.

An increase of £1,456 on the grant account is very heavy, and for the Fund to extend its work as well as continue to help those already on its books necessitates an urgent appeal that subscriptions and donations in 1929 shall be not only maintained, but greatly increased. Cheques should be sent to the Honorary Treasurer, 11, Chandos Street, Cavendish Square, London, W.1.

At the last meeting of the committee £763 was voted to thirty-five applicants. The following short account of a few typical cases may serve to show how deserving are the persons helped by the Fund.

Widow, aged 54, of M.B. Owing to the lack of any special training is unable to earn more than £1 a week. Voted £36 in four instalments. Widow lives rent free in one room.

Daughter, aged 68, of L.R.C.S. and L.S.A. Has supported herself for twenty-one years. Earning at first £16 a year, afterwards £36, rising to £50 and then £80. Her employer has recently died, and, owing to her age (68), she cannot now find work and is practically destitute. Only income old age pension, £26 a year. Voted £36 in four instalments. Other charities will be asked to assist. Applicant at present living with her nephew.

Daughter, aged 66, of M.D. On death of her parents was left eldest of four children and very badly provided for. Has supported herself by teaching until her health gradually gave way at 65. Her only income is £61 a year. Voted £36 in four instalments.

Widow, aged 71, of M.D. Has supported herself by keeping a private school, but owing to her age (71) and to her out-of-date methods of teaching she has practically lost all her pupils, and is almost destitute. Income £65. Voted £36 in four instalments. Other charities are now interested in this case and will help.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58, Great Marlborough Street, W.1.

Union of South Africa.

[FROM OUR CORRESPONDENT IN CAPETOWN.]

Prevention of Tuberculosis.

AT a meeting of the Association for the Prevention of Tuberculosis held at Capetown on November 15th, 1928, a report on the work of the executive since the reconstitution of the association in March, 1928, was received. The president, Dr. D. P. Marais, said that its activities were not so well known in Capetown as might be expected, this being due to the fact that the association was concerned more directly with work in the up-country districts. Propaganda work was being done through posters and literature, and arrangements were made for speakers to give addresses in connexion with health weeks, of which only recently there had been a very successful one at Paarl and another at Beaufort West. A native poster, published by the South African Health Society at Lovedale, together with suitable literature in the native language, had been distributed in the native territories. About one thousand of these were sent out to ninety-three missionaries and ministers, and several of those to whom they were sent out had promised to assist the association's work in the territories. The

Metropolitan Poster Advertising Company of Capetown had been kind enough to undertake to display the association's posters free of charge, when opportunity offered between contracts, on the hoardings of Capetown and suburbs. The police authorities, he continued, had been requested to enforce more strictly the regulations relating to spitting in public places, and a satisfactory acknowledgement had been received. New brass insets for the pavements had been supplied to the municipality. A bioscope film, entitled "Delay is Dangerous," was imported from America at a cost of about £16. The film was passed by the Board of Censors, and was recently sent to Beaufort West, to be shown in connexion with the health week there. The African Films Trust had been kind enough to promise to grant every assistance in the public exhibition of the film when it was returned. Negotiations were now proceeding with the South African Red Cross Society at Johannesburg for the purchase of other films. These negotiations were the outcome of correspondence with the National Tuberculosis Association of England and the Red Cross Societies at Paris, which took considerable time owing to the distance. It was hoped that it would be possible to have incorporated with the imported film a film of local interest, showing some of the local clinics, and life and work at the Nelspoort Sanatorium. It was also intended to have lantern slides of the latest poster made if the cost was found to be reasonable.

Edinburgh University Medical Graduates' Club.

The second annual dinner of the Edinburgh Medical Graduates' Club was held on December 7th, 1928, at the Western Province Sports Club, Kelvin Grove, Capetown, under the chairmanship of Dr. C. H. Kruger. Among those present were Mr. C. E. Jones-Phillipson, Professor W. A. Jolly, Professor W. Campbell, Drs. D. P. Marais, J. S. du Toit, J. Smith, A. J. Ballantine, F. Krone, F. H. Dommisse, A. W. S. Sichel, S. J. Rom, D. H. Wessels, D. Dowie Dunn, Mr. W. Lennox Gordon, and Dr. Louis Bosman. Besides the toast of "The King" there was only one other, "Alma Mater," which was proposed by Mr. Lennox Gordon, and Professor Campbell replied. An amusing feature of the dinner was the naming of each place at table after some old Edinburgh student haunt, the member sitting there being invited during the evening to recount his reminiscences of the particular place he happened to represent. Before dispersing, a ballot was held to ascertain which of these old haunts was the most popular, and a small memento was presented to the member who occupied the corresponding seat at table. Though the gathering comprised a very small proportion of the old Edinburgh graduates resident in Capetown and the surrounding districts, who number about 110, the evening proved entirely successful. It was originally the intention of the committee responsible for the dinner to entertain as guest of honour Sir Arthur Conan Doyle, a medical alumnus of the University of Edinburgh, at present on a visit to South Africa, but to the regret of all he found it impossible to be present. The club, which was formed only a year ago with the object of fostering a spirit of comradeship among Edinburgh graduates, and is purely a social one, has the following officials: president, Mr. E. Barnard Fuller, F.R.C.S.Ed.; vice-presidents, Professor W. A. Jolly and Dr. C. H. Kruger; honorary secretary and treasurer, Dr. F. Krone.

New Nursing Home.

The foundation stone was laid on November 3rd of the Volkshospital, the ceremony being performed by the Rev. G. J. Hugo, Moderator of the Dutch Reformed Church Synod. The chairman of the hospital committee, the Rev. F. X. Roome, referred to the valuable work that had been done at the Deaconess and the Monte Rosa hospitals, which were instituted, and were still being run, by the Dutch Reformed Church. The financial position, he stated, was sufficiently favourable for them to proceed with the work. They had £35,000 in hand, together with £3,500 bequeathed by the late Mr. Conradie of Worcester, and they required another £17,000 to provide for a building with 35 beds. Should they decide to add another 15 extra beds an additional £11,000 would be needed. On the spacious grounds (which had been bought for £6,000) quarters could be built for £10,000, by which the number of beds would be increased to 75. Their immediate aim, however, was not to have a separate building for the nurses, nor would the extra story be built, unless the necessary public support was forthcoming. The Volkshospital was really a hospital nursing home, continued Mr. Roome, being designed on the plan of a general hospital—with full equipment, including an x-ray room, and plenty of space for further development—which could be utilized by medical men, specialists, and others. The nurses would be bilingual, because the doors of the "home" would be open to all sections of the European population, and it would add to the comfort of a patient to be attended to in the language he or she knew best. Dean Lavis also addressed the gathering, and paid a glowing tribute to the great work carried out by the Dutch Reformed Church in the hospital institutions under its aegis, where there had never been any suggestion of religious discrimination. That the need existed for more hospitals, he remarked, there could be no question; it was a by-word and a scandal. Among those present at the ceremony were the Rev. J. P. van Heerden, Senator F. S. Malan, Rev. S. P. Fouche, Sir Carruthers Beattie (Principal of the University of Capetown), Dr. D. P. Marais, Dr. J. S. du Toit, Mr. P. M. Daneel, Dr. D. H. Wessels, and Mr. J. Luckhoff.

Snake Venom "Cure" for Epilepsy.

Publicity has been given lately in the lay press to a grievance ventilated by Mr. F. W. FitzSimons, director of the Port Elizabeth Museum, with regard to his claim to have produced a cure for epilepsy in the shape of snake venom. In a letter which appeared in the *Cape Argus* on November 27th, 1928, Mr. FitzSimons states:

"My attention has just been called to a paragraph in your journal to the effect that Sir Spencer Lister has stated that there was no foundation for my statement that laymen are debarred from publishing scientific articles in the medical journals. Early in 1921 an article of mine, entitled 'Snake venom for epilepsy,' was refused publication by the then *South African Medical Record* on the ground that the journal did not publish contributions by laymen. It was only owing to the special request of the Secretary for Health for the Union that this article was eventually published. Just recently I applied for formal permission to read a paper on 'Snake venoms and their therapeutic value' before the Medical Association at the forthcoming conference at Port Elizabeth, and I had already worked for a considerable time on the preparation of the paper. The official reply to my written application was to the effect that 'according to the regulations, papers may be read before congress only by members of the Medical Association of South Africa.'"

Meanwhile the editor of the *Journal* of the Medical Association of South Africa had written to the *Eastern Province Herald*, a daily paper published in Port Elizabeth, to the following effect:

"As editor of the *Medical Journal*, and as secretary of the Medical Association of South Africa (British Medical Association), I emphatically contradict Mr. FitzSimons's assertion that there is any rule that prevents a layman from publishing an article in the medical press or reading a paper before a meeting of my Association. There is no such rule. My journal has often printed articles written by laymen, and laymen have read papers before my Association. I have refused Mr. FitzSimons's article on the treatment of epilepsy by snake venom just as I should refuse to publish one on the treatment of epilepsy by hydnocarpus or kliprsweet. Both substances have had a fair and extended trial by the medical profession, and there can be no question whatever that they are no more 'cures' for epilepsy than common salt is a cure. For the same reason, possibly, the local branch of the Medical Association of South Africa has declined a paper on the subject. So far Mr. FitzSimons has quoted nothing that is new or that has not been told years ago."

India.

Health Propaganda in Madras.

INCREASING attention is being given in various parts of India to the development of propaganda work in connexion with the public health services as a means of educating the masses and disseminating knowledge of hygiene and of factors relating to the causation and prevention of disease. In the Presidency of Madras a separate section of the Public Health Department was constituted about eighteen months ago to deal with this work, and the report of the Director of Public Health for 1927 contains an interesting account of the propaganda activities of the district health staff and other agencies. An auxiliary committee has been

formed to preserve contact between the department and non-official bodies. In the course of the year over 91,800 lectures were given in 41,089 centres to audiences aggregating over 5,800,000 persons, and including about one-eighth of the population of the Presidency. Most of the lectures were given to labourers in rural areas by health inspectors and municipal sanitary inspectors, and were therefore of the simplest kind. It has been found that lectures accompanied by lantern or cinematograph displays are, as might be expected, the most popular and effective, and an endeavour is being made to equip every health inspector with a lantern. The Madras Health Council is lending valuable assistance in maintaining a supply of slides appropriate to the localities in which they are to be shown, but it has proved difficult to secure suitable films, and it is probable that the health department will in time find itself obliged to add film production to its activities. Large quantities of propaganda literature have been prepared and circulated, while the enactment of health dramas—of which a considerable number are in existence—by schoolboys has been found a valuable method of educating the public. Advantage is taken of large gatherings at fairs, festivals, and markets to further the work by the organization of exhibitions, lectures, lantern demonstrations, and the distribution of literature, while health instruction in the schools is being developed as rapidly as circumstances permit. The report of the Health Department expresses the view that the efforts so far made have been reasonably successful, but calls attention to the continued neglect of health propaganda in most of the municipal towns. It is added that in no town without a health officer is sufficient attention paid to this subject, and that this fact alone warrants the suggestion that the Government should insist on the appointment of a health officer in every municipality in Madras.

Extension of Medical Services in the Punjab.

Considerable progress has been made in recent years in the provision of facilities for medical attention in the Punjab. In 1927 the number of hospitals and dispensaries of all kinds in the province increased from 780 to 885, this being accounted for mainly by the creation of new rural dispensaries. Towards the end of 1925 the Punjab Government sanctioned the adoption of a scheme providing for the establishment of 375 new dispensaries in this category; of these 110 were opened in 1926 and 84 last year, leaving 181 to be established subsequently. In 1927 progress was somewhat slower than before, owing to the fact that certain district boards found the Government grants for construction, equipment, and maintenance insufficient to cover the expenditure involved. In other directions progress was less marked, and only two hospitals were taken over by the provincial Government from inferior authorities. Preparations were, however, made to accelerate the provincialization of a large number of hospitals. As in other parts of India, there is a pressing need for more women doctors in the Punjab; efforts are being made to afford improved facilities for the medical education of women, to extend female hospital accommodation, and to employ an increased number of women in hospitals and other branches of the medical service. Several new institutions for women have been established, or are contemplated. The figures given in the annual statement for 1927 of dispensaries and charitable institutions in the province illustrate at once the need for increased facilities for treatment and the extent to which advantage has been taken of the new services. There was an increase of 870,460 on the previous year's figure in the number of patients treated, the total for 1927 being 9,246,281. Of this number 1,418,188 were treated at rural dispensaries, as compared with 641,258 in 1926, an increase of 776,930.

Development of Child Welfare Work.

The annual public health report of the Central Provinces and Berar for 1927 calls attention to the development of maternity and child welfare work in that area, where special efforts have been made to secure a reduction in infantile mortality, which is higher than in any other province in India. It is the policy of the provincial Government, as funds permit and local assistance is forthcoming, to provide a well-equipped women's hospital, or women's branch of a main hospital, in each district. Meantime, the establishment of welfare centres is being encouraged, and satisfactory results have accrued from the activities of welfare organizations in the capital city of Nagpur, where the movement has naturally made the greatest headway. At the end of the year there were twenty-one centres affiliated to the provincial Red Cross Welfare Committee, which is entrusted with the direction of the movement, and it was expected that the opening of the full complement of thirty centres sanctioned for the province would be completed within a few months. The committee undertakes the training of health visitors and *dais*, and the arrangement of "baby weeks." In Nagpur seven centres have been established—the first in 1921—three being under the municipality, two (including a training centre) under the Welfare Committee, and two under branches of the Red Cross Society. It is considered that the ideal condition would be to have one small centre in each of the twenty-four circles into which the city is divided. The existing organization has, however, permitted the visiting and revisiting during early infancy of 4,387, or 63 per cent. of the total of 6,885 births recorded in the city. It has been found that the mortality rates per 1,000 births in respect of infant deaths under 1 month were 122.00 for the entire town, 109.64 for the cases visited, and 133.16 for other cases. These statistics relate only to the three municipal centres, and the "other cases" therefore include a number visited by other agencies, so that it is assumed that the mortality among those who were actually unvisited is probably even higher than the figures suggest. The mortality among cases visited is less than half the provincial average.

Shillong Pasteur Institute.

During 1927, 1,142 patients visited the King Edward VII Memorial Pasteur Institute and Medical Research Institute at Shillong, in Assam, for antirabic treatment, and among them there were 11 deaths, giving a mortality of 0.96 per cent. A classification of patients according to the period which elapsed between the time of the bite and the time of arrival at the Institute brings out the importance of early treatment. Lieut.-Colonel J. Morison, the director, in his annual report, states that among the 316 cases which arrived during the first four days after the bite there was one death; among the 240 patients who arrived five, six, or seven days after the bite there were three deaths. These patients died in from twenty-five to thirty-one days after being bitten, and in them, and in another case which arrived ten days, and ended fatally thirty-eight days, after the bite there was no evidence that treatment had any effect. The interval between the bite and death in the remaining six fatal cases was from 52 to 156 days, and it is suggested that in this group the treatment may have had a delaying effect. While the numbers are small, Colonel Morison points out that they illustrate a feature of antirabic treatment of which two explanations have been given, these being (*a*) that in the first group the virus had at once been planted in a nerve where it was shielded from the action of the protective bodies generated by the treatment, and (*b*) that there are strains of virus against which the strain of vaccine used in a particular institute has no effect. The general result shown by the year's figures is that among Indian patients who arrived within the first week after being bitten the mortality was 0.57 per cent., while among those who arrived after longer intervals the mortality was 1.77 per cent. With the success in the treatment of kala-azar with antimony compounds, and the increased accommodation available elsewhere for patients suffering from this disease, only doubtful and difficult cases are now received at the Shillong Institute, and Colonel Morison therefore suggests that the experimental ward hitherto used for kala-azar patients should be opened for cases of other diseases, such as chronic dysentery and sprue, on which research work is now being carried out.

Ranchi Indian Mental Hospital.

The accommodation for patients in mental hospitals in India appears in a number of cases to be inadequate. Reference was made in the *Journal* of October 27th (p. 763) to complaints of overcrowding in such institutions in Madras, in the Central Provinces, and in the Punjab, and

the report for 1927 on the working of the Ranchi Indian Mental Hospital, which receives patients from the provinces of Bengal and Bihar and Orissa, states that the congestion continued during the year. There is accommodation in the hospital for 1,286 patients—1,014 males and 272 females—and the daily average number under treatment was 1,410—1,182 males and 228 females. Owing to the lack of accommodation it was necessary to reject a considerable number of applications for admission as paying patients, while hydrotherapy could not be practised extensively as no suitable place was available. Early this year the management committee met to consider the questions of relieving congestion and providing additional buildings and staff, and its recommendations are receiving the attention of the local Government.

Scotland.

Passing of the Board of Health.

THE last meeting of the Scottish Board of Health was held in Edinburgh, on December 28th, 1928, and on January 1st, 1929, the functions and duties of the Board were taken over by the new Department of Health for Scotland. Dr. Walter Elliot, M.P., presided at the meeting. Reference was made to the retirement of Sir James Leishman, who was chairman of the Board, and the members resolved to place on record their high appreciation of his valuable services. Dr. Elliot recalled that Sir James Leishman first entered public life in 1903 as a member of the Edinburgh School Board, and in this capacity was specially associated with the development of evening continuation classes in Edinburgh. In the same year he became a member of the Edinburgh Town Council, and he afterwards continued to exercise an interest in educational matters as a representative of the town council on various educational institutions of the city. After six years' service on the town council he was elected to the important post of city treasurer in 1909. When the National Insurance Act was passed in 1910, and the National Health Insurance Commission was entrusted with the task of bringing its provisions into operation in Scotland, Sir James Leishman was appointed chairman. To this difficult task he brought organizing ability and driving power, which were invaluable in the successful inauguration of the scheme, and recognition of these services was made by the honour of knighthood being conferred on him in 1914. Since 1925 he had also been closely connected with the scheme of contributory pensions for widows, orphans, and aged persons, which was interwoven with that of health insurance by the passing of the Contributory Pensions Act in 1928. When the National Health Insurance Commission was merged with the Local Government Board of Scotland in the Scottish Board of Health in July, 1919, Sir James Leishman became a member of the new Board, and in March, 1928, he was appointed chairman. In this capacity, Dr. Elliot concluded, he shared in the responsibility for the administration of a great variety of subjects that came under the power of the Board in connexion with the various health services of Scotland.

Proposed Radium Institute for Scotland.

At a meeting of the board of management of the Royal Infirmary, Edinburgh, held on December 17th, 1928, it was decided to take steps for the establishment of a radium institute for the treatment of patients suffering from cancer and other conditions amenable to radium. For this purpose the managers proposed to reconstruct "Beechmount," a large house on the southern slope of Corstorphine Hill, which was bequeathed to the Infirmary some years ago. The managers also resolved, if necessary, to devote from the unrestricted funds of the Infirmary a sum of £40,000 to carry out this scheme and to provide accommodation for some thirty in-patients. It is intended that the institute should serve more especially for Edinburgh and the south-eastern area of Scotland. This is the first to be proposed in Scotland. The services of the staff of the [illegible]ment and other facilities of the Royal [illegible] for patients in this institute, where it is proposed that a relatively large quantity of radium shall be available under the care of an expert physicist.

The General Practitioner and the Public Health Service.

In his last annual report as medical officer of health for Aberdeen Dr. J. Parlane Kinloch, whose appointment as chief medical officer to the new Department of Health for Scotland was announced in the *Journal* of November 17th, discusses the relationship of the general practitioner to the public health organization. After dealing with the present inadequacy of hospital provision, which he suggests will be largely remedied by the unification of health services proposed by the Government, Dr. Kinloch states that there has been legitimate criticism of the failure to link the general practitioner with official services of his area. With every extension of the official health service the tendency has been to appoint whole-time officers to undertake the work, and he recalls that the British Medical Association is considering how the general practitioner may be enabled to participate in the official health service. The encroachment of public medicine on private practice, he states, is already practically complete; it is the declared policy of every political party to achieve an adequate health service for the whole community, and accordingly it would appear to be essential to incorporate the medical practitioner within the scheme. He expresses his personal conviction that "however admirable the administrative machinery of the Health Department may be, however adequate the hospital provision, however adequate the specialist, clinical, and laboratory aids to diagnosis and treatment, nevertheless the public health organization will fail to provide an adequate medical service for the community until such time as the general medical practitioner becomes an executive medical officer within the service." Dr. Kinloch contends that if the Government proposals are accepted they are at the parting of the ways, and that it is for the local authorities, the medical profession, and the public to determine whether the time is not overdue when the general practitioner should be re-established in his position of full responsibility as family doctor, responsible for watching over the family health, for the prevention of disease, and for utilizing to that end the whole of the efficient machinery that the local authority has provided. He is convinced that this is possible, and that, just as there must be complete interlocking between the work of the statutory health authority and the voluntary agencies, so the co-ordination of the work of the statutory health officer and the private medical practitioner within a complete medical organization will provide the adequate service that is the desire of everyone interested in social welfare.

Presentation to Dr. John Wilson.

On the occasion of his retirement, and on the completion of his fiftieth year in practice in the district, Dr. John O. Wilson was recently entertained at a public dinner in Huntly, when gifts were presented to him and to his wife. In the course of the proceedings reference was made to the fact that the medical connexion of the family with Huntly had lasted for over one hundred years, Dr. Wilson's father having been indentured as apprentice to a surgeon in the town in 1828, and having been joined in practice there by his son fifty years ago. Provost Christie, who presided, praised the readiness with which Dr. and Mrs. Wilson had always assisted any worthy cause; the people of Huntly owed a deep debt of gratitude to them. Mr. Robert Milne, in presenting Dr. Wilson with an inscribed gold watch and a wallet of notes, recalled the difficult conditions which prevailed in medical practice in the days before the advent of the motor car. No one, he remarked, had ever heard the doctor complain of his life or of unreasonable or irritating patients; he had always been the soul of geniality, even temper, and kindly personality. His poorer patients had received the same care and unremitting attention as the well-to-do, and he had made many a visit expecting no reward but gratitude. In his public appointments he had worked quietly, but none the less efficiently. After referring to Dr. Wilson's connexion with the Volunteer and Territorial Forces, Mr. Milne expressed the hope that he would have many years to enjoy his well-merited leisure. Proposing the toast of

"The Guests," Dr. Taylor of Keith said that he had attended the jubilees of several medical practitioners who were almost all decrepit. On the present occasion they welcomed one who was still gay and debonair, and who still had the tonic smile with which he greeted his friends and patients fifty years ago, a sprightliness of gait, and a seat in the saddle which would be the envy of many a man twenty years younger. Dr. Wilson, by his kindness and skill, had endeared himself to thousands of patients in Strathbogie and the district, and had always been most popular with his colleagues. In replying, Dr. Wilson expressed his warm appreciation of the kindness and honour shown towards him, and in a witty speech discussed the great developments in medical practice in his lifetime, recalling also many amusing incidents in his father's career in Huntly.

Presentation to Dr. W. G. Stevens.

Dr. W. G. Stevens, who is retiring from the post of medical officer of health for the burgh of Renfrew after fifty years' service, was, on December 26th, 1928, made the recipient of a presentation, when Provost M'Gregor handed over to him an address and cheque as a mark of appreciation by the town council and his friends of his long and faithful service in the burgh as medical officer of health and factory surgeon, and also as a medical practitioner. Dr. Stevens is now 88 years of age, and was a student under Lister when the latter took up his post in 1860 as professor in Glasgow Royal Infirmary. During his long career in Renfrew Dr. Stevens took an active interest in the local Volunteer and Territorial Forces, having been surgeon lieutenant-colonel to the 2nd Volunteer Battalion Argyll and Sutherland Highlanders, and afterwards lieutenant-colonel in the Territorial Sanitary Service of the R.A.M.C. He holds the Volunteer decoration for long service. Mrs. Stevens was presented with a gold brooch.

Edinburgh Samaritan Society.

The fiftieth annual report of the Samaritan Society of the Royal Infirmary of Edinburgh has just been issued. The society was founded in 1879 to assist the families of patients by providing clothing and travelling expenses, and to help patients leaving the Infirmary by finding work for them, and in other ways. Patients in other hospitals of the city are now included in the benefits of the society, which also undertakes a share in general social service work relating to patients under treatment in the wards. In 1908 the society received a bequest of £19,000, which considerably strengthened its position, and it is further supported from year to year by voluntary contributions. The society now maintains three almoners, and during the past year dealt with 441 new cases, against 393 in the previous year, the visits paid by the almoners being 1,456, as against 1,298 in 1927. In the past year its expenditure was £202 in excess of its income, and an appeal for new subscribers is therefore being made.

Ireland.

The Future of Medical Teaching in Dublin.

DR. R. J. ROWLETTE, who is president of the Section of Medicine of the Royal Academy of Medicine in Ireland, delivered recently a thought-provoking address on the aims and methods of medical teaching in Dublin. He said that the primary duty of a controlling body, such as the General Council of Medical Education and Registration, or the Irish Free State Medical Registration Council, was to satisfy itself that the educational course and examination tests were such as to ensure the possession by those obtaining admission to the *Register* of a degree of knowledge and skill requisite for the efficient practice of medicine, surgery, and midwifery; but a council had to go further, and to assist the qualifying bodies by direct advice. The General Medical Council, in its life of seventy years, had maintained a sound standard, but it had inevitably tended also to produce an undesirable uniformity. Too strict standardization and too close uniformity hampered individual thought and checked progress. The Council had naturally been most concerned with English conditions, and the Irish Council would have to consider whether the needs of those about to practise in Ireland required any special attention, and to ensure full advantage being taken of the local special facilities for teaching. Some changes made in recent years under the influence of the General Medical Council were open to criticism: the extrusion of the preliminary sciences to a pre-registration period interfered with the cultural education of the student; the insistence on certificates in a large number of special subjects prevented a due appreciation of the fundamental principles of the great unities of medicine and surgery, and encouraged specialization prior to qualification; in midwifery and gynaecology the standard traditionally required by the Dublin schools had been lowered in recent years. The most distinctive feature of Dublin teaching was its practical character, and its heart was the resident student system; it was worth considering whether that system should be made compulsory. At present sufficient care was not taken to ensure that students attended hospital regularly. The aim of clinical teaching should be to render the student familiar with the condition of the patient by first-hand observation, and to let him see and practise the several methods of diagnosis and treatment; observation of the course of the disease from day to day was necessary, but wandering from hospital to hospital in the early clinical years prevented this consecutive study. In the later years, however, such wandering broadened the mind. The special facilities which Dublin possessed for the study of midwifery and ophthalmology should be fully used, but, at present, there was little provision for teaching gynaecology. The large number of small hospitals in Dublin, though in some respects advantageous, had certain grave disadvantages. The small amount of material at the disposal of any clinical worker hampered research. The organization of the smaller hospitals was necessarily faulty in that they were not supplied with adequate auxiliary staffs, and there was a tendency to replace personal consultation by a series of written communications. Medical education in Dublin was likely to lag behind that in other centres unless a method was found of amalgamating some of the smaller hospitals. It ought to be considered whether there were not certain definite needs of Ireland which should receive particular special consideration in an Irish school. In two subjects the Irish practitioner required special knowledge—midwifery and public health. The people of Ireland had a right to demand a higher standard of knowledge than the schools had yet required. There was almost no provision for research in Ireland, and without research education became lifeless. Recently the Rockefeller Foundation had given generous help to both universities, but much more was needed. Unless there was unanimity in the demand for funds, wherever the demand was made, success could not be expected. An attempt made by the Academy a few years ago had failed to arrive at unanimity, but another attempt on different lines might have more success. The Dublin School had a great past, it had stood the test of time, and had shown adaptability to changing circumstances. In the future it could show further powers of growth and adaptation, but it was necessary to watch for signs of weakness, to promote development where this was desirable, and to remember that a school was a living thing.

Sir William Taylor (President of the Royal Academy of Medicine) emphasized the importance of reducing, not the teaching, but where possible the cost of it to the student. He deprecated in strong terms any tendency to specialization on the part of students of medicine, and urged that this should not be encouraged till after qualification. The study of large groups of cases of one disease by doctors particularly interested in that disease tended to the advantage of medical men and the general public; amalgamation of hospitals was necessary for such study to be practicable, and if the Dublin School was to regain its former position as a pioneer in medicine such amalgamation was necessary. Professor H. F. Moore emphasized the importance of maintaining and increasing close co-operation between the Dublin schools of medicine; he foresaw many advantages which would follow from it. Professor T. G. Moorhead deprecated any revolutionary changes in the student's curriculum, the object of which should be to

impart a thorough knowledge of the essential principles of medicine, surgery, and midwifery. Sir John Moore defined the status and powers of the General Medical Council; its position was purely that of an advisory body, and it had no power to alter the curriculum of any licensing body. Dr. Bethel Solomons advocated strongly a period of residence in a maternity hospital.

Vital Statistics for the Irish Free State.

The report of the Registrar-General of the Irish Free State for 1927 states that the estimated population at the middle of the year was 2,957,000; the population according to the 1926 census was 2,971,992. Deaths in 1927 numbered 43,677, or 1,937 more than in the previous year. The number of emigrants in 1927 was 27,309, and of immigrants 2,084. The death rate was equivalent to a rate of 14.77 per 1,000 of the estimated population, which is lower than the average for the previous ten years, but higher than the rate for 1925 (14.62) and 1926 (14.05), the increase being due chiefly to influenza and heart and respiratory diseases. In the epidemic diseases group Dublin county borough, with 1.59 per 1,000, had the highest rate of any county or county borough; the rate for the whole country was 0.52. The number of deaths from tuberculosis was the lowest yet recorded, deaths from all forms of the disease numbering 4,301, or 1.45 per 1,000. The corresponding rate in Northern Ireland was 1.41, in England 0.97, and in Scotland 1. The number of deaths from cancer—3,113—in 1927 was the highest yet recorded, being 92 more than in 1926; the increase occurred entirely among men. Deaths from bronchitis numbered 2,610 and from pneumonia 2,883, showing increases of 177 and 519 over the 1926 figures. The number of deaths of infants under 1 year of age registered in 1927 was 4,254, or 71 per 1,000 births, as compared with 74 in 1926, and an average of 75 for the ten years 1917–26. In recent years the infant mortality rate has tended to increase. The infant death rate in rural areas was 56 per 1,000 births, in urban areas 99 per 1,000, and in Dublin county borough 123 per 1,000. For Northern Ireland the infant mortality in 1927 was 78 per 1,000, for England and Wales 70, and for Scotland 89.

Galway County Hospital.

Galway Hospital Committee has adopted the recommendations of the visiting committee and the medical staff as to the filling of the vacancy created by the death of Dr. Michael Dexitt, visiting physician to the hospital. It is proposed that the salary, heretofore £600, be divided equally between the surgical and medical officers, giving £150 each to the surgeons, Mr. M. G. O'Malley, F.R.C.S., and Dr. R. B. Mahon, as annual honoraria, to cease when they no longer hold chairs in the University. The committee further recommended that two physicians be appointed—one to be honorary, for the present, provided he holds a chair in the University. The salary for the paid physician, it is suggested, should be £300 a year, provided he does not hold a chair in the University; if at any period he is allocated to a part-time chair the salary payable from the rates is to be reduced to £150 a year. The position is restricted to male persons under the age of 40, with at least five years' practice, and holding the degree of M.D. and the D.P.H. The appointment will be part-time, and the holder must practise only as a physician —both inside and outside the hospital—while his salary remains at £300.

Appointments at Coombe Hospital, Dublin.

Dr. Timothy M. Healy, late Assistant Master of the Coombe Hospital, and son of Mr. T. M. Healy, K.C., was recently elected Master of the Hospital for the usual term of seven years at a special meeting of the board of guardians and directors. Dr. Healy graduated M.B., B.Ch., and B.A.O. at the National University of Ireland in 1921. Dr. Ninian Falkiner has been elected by the directors to the post of gynaecologist to the hospital in succession to the late Dr. L. Cassidy. Dr. Falkiner was Assistant Master in the Rotunda Hospital for the maximum period of three years, and was mainly instrumental in organizing the pre-natal clinic in connexion with that hospital.

Professor D. T. Barry.

The President of the French Republic has appointed Professor David Thomas Barry a Knight of the Legion of Honour. Professor Barry, who has held the chair of physiology at University College, Cork, since 1907, received his medical education at the old Queen's College there, in Liverpool, and also in Paris. He graduated M.B., Ch.B. R.U.I. in 1894, proceeding M.D. in 1905; four years later he was admitted to the Fellowship of the Royal College of Surgeons of England.

England and Wales.

Home Service Ambulance Committee.

THE report of the Home Service Ambulance Committee of the Joint Council of the Order of St. John and the British Red Cross Society for the third quarter of 1928 shows that at the end of September there were 294 of the committee's ambulances in service, and 61 affiliated stations, making a total of 355; the number of patients carried during the quarter was 29,656. The report refers to the advantages gained from the adoption of the county as the basic unit for the organization of the service, and so thoroughly is the country equipped that there should now be no part which cannot be reached by a motor ambulance within a reasonable time. In connexion with finance, however, it is noted that there does not seem to be a universal appreciation of the extent of the support that, by energy and perseverance under a well-organized system, may be obtained from the general public for ambulance work. While an agricultural county may achieve such success as to be able, largely from its own resources, to provide for the replacement of its ambulances as they become worn out, other counties experience difficulty in providing adequately for maintenance, and, when new ambulances are required, appeal to the committee for the whole cost. The hope is expressed that all county representatives and committees will endeavour so to organize their areas that they may look to the future, not only without fear as to the permanence of the service as it is, but with the assurance that there shall be steady progress in the provision of improved ambulances, and consequently greater efficiency of service. The quarter under review proved a particularly busy one in the matter of road accidents, in connexion with which 2,852 cases were carried in the ambulances. There was a considerable increase in the number of roadside first-aid stations manned by members of the associated organizations during holidays and week-ends. At one of these stations a roadside appeal to motorists for assistance in meeting the cost of providing a hut, surgical equipment, and a telephone yielded in two days nearly £150.

Smoke Abatement League.

During the first part of the year ending June, 1928, the lack of secretarial assistance hindered the development of active propaganda work by the Smoke Abatement League of Great Britain, but some progress was made later. The annual report of the league mentions that at a conference last March, in Manchester, held jointly with other interested bodies, Dr. H. A. Des Voeux read a paper on the Public Health (Smoke Abatement) Act, 1926, the subsequent discussion being opened by Dr. R. Veitch Clark. A conference under the auspices of the Scottish branch was held in Glasgow in May, when it was decided to press for the application of a similar measure to Scotland. Efforts are being made to secure a wider measure of support for the work of the league by means of newspaper publicity, lectures, and correspondence with members and prospective members of municipal corporations. An appeal for subscriptions, which was addressed to about 290 local authorities, did not, unfortunately, secure a very cordial response. After the close of the year under review a conference was held at Harrogate, on September 29th and 30th, when the secretary of the league, Mr. Arnold Marsh, presented a report on an inquiry into the experience of users of solid smokeless fuels. This report contains an

interesting summary of the advantages and disadvantages encountered in the employment of such substitutes for coal. In general, and notably in respect of heat efficiency, economy, and cleanliness, users have found the various brands of smokeless fuel on the market superior to coal. Copies of the report, and of a paper on the influence of air pollution on vegetation, read on the same occasion by Mr. W. W. Pettigrew, general superintendent of the Manchester Parks Department, may be obtained from the offices of the league, 23, King Street, Manchester. The British Medical Association is represented on the council of the league by Dr. G. Clark Trotter and Mr. Bishop Harman.

London By-Laws for Nursing Homes.

By-laws with regard to nursing homes in the county of London under the Nursing Homes Registration Act, 1927, have been approved by the London County Council. The by-laws are based on the model laws issued by the Minister of Health, with certain alterations, to which the Minister sees no objection. One of the alterations is the substitution in the by-law No. 1, to meet the special circumstances of London, of Section 55 of the Public Health (London) Act, 1891, for the Infectious Disease (Notification) Acts, 1889 and 1899. The other alteration is the addition of a proviso to the by-law No. 3. This by-law lays it down that the keeper of a nursing home shall keep a case record giving a daily statement of the health of every patient in the home suffering from acute illness, and, if it is a maternity home, of every mother and infant, as well as a periodical statement of health of any other patient. To this the London County Council adds the proviso, not in the model by-law, "provided that such statement need not include any medical record relating to the patient." It is proposed to append to the by-laws suitable notes referring to the provisions of the Act as to the inspection of premises and the keeping of records, the definition of a maternity home, and the penalties for infringement of the by-laws. The by-laws, after they have been confirmed by the Minister, will be enforced by the Council.

Instruction in Health Work and Nursing at Hull.

With the approval of the Ministry of Health a scheme of training for health visitors has been arranged at Hull. Theoretical instruction will be provided at the University College, while practical teaching will be given in the public health department of the city. During the practical part the students will rank as probationer health visitors, and receive a salary from the corporation. The number of probationers under the Hull Public Health Department is limited to six annually. They are required to have had three years' training in a general hospital approved by the General Nursing Council for England and Wales, to possess the certificate of the Central Midwives Board, and to undertake to remain as probationer health visitors in the service of the Corporation of Hull for a period of twelve months. They will obtain experience of the work in the school medical and antituberculosis departments, as well as of the usual activities of a health visitor. It is proposed also to provide instruction at University College, Hull, in certain parts of the examination for the diploma in nursing of the University of London. The lectures will cover the subjects of Part A of the syllabus, which must be taken by all candidates, and also most of Part B, Section 8 (elementary economics, sociology, and hygiene in relation to the duties of public health nurses). If there is sufficient time a course in the methods of teaching and the elements of educational psychology will also be provided. Further information may be obtained from the secretary, University College, Hull.

Changes in Medical Practice.

Dr. R. W. Marsden took as the subject of his recent presidential address to the Manchester Medical Society "Changes in medical practice in the last forty years." He said that during the period under review a prominent feature of medical practice had been the increased attention given to prophylaxis. He instanced in this respect the wide ramifications of the public health service, and suggested that by its continual encroachments on private practice it might in the end necessitate the formation of a State medical service. He then referred to the changes which had taken place in the manifestations, management, or prevalence of certain diseases; to the rarity of once common diseases such as chlorosis, cirrhosis of the liver, polyneuritic psychosis, delirium tremens, and gout, attributing the first-named to notable change in social ideas and customs in the female sex, and the others to a more or less compulsory increase in sobriety. Dr. Marsden next spoke of the apparent decline in frequency of "dyspepsia" and "indigestion," and the apparent increase in frequency of ulceration, particularly ulcer of the duodenum, and its occurrence more especially among young male adults. The introduction of *x*-ray examination with opaque meals, and the enormous advances in the surgery of the abdomen, had, however, so revolutionized work and ideas on these subjects that it was difficult, if not impossible, to compare the conditions of forty years ago with those of the present time. Turning to the great increase in the number of cases of neurasthenia and of the various psychoses, he expressed the opinion that to a large extent this was a direct or indirect consequence of the war. Dr. Marsden then mentioned the changes in our knowledge of venereal diseases and their treatment; the introduction of serums and vaccines; the value of lumbar puncture; the advances resulting from the vast science of immunology; the importance and complexity of the various blood examinations; the attention given to the endocrines and vitamins; the use of artificial sunlight and other rays, as well as of radium, and the various forms of electrical energy. Finally, he asked whether there was any evidence of a new disease having appeared, citing particularly encephalitis lethargica and trench fever, and came to the conclusion that it could not be said that these were new developments.

Public Conveniences in London.

An inquiry into the public conveniences of London, their number, distribution, adequacy, and sanitary condition, has just been conducted by officers of the London County Council. The earliest general legislation on this subject was embodied in the Public Health Act, 1848, but it was not until the Public Health (London) Act, 1891, that there began to come into existence the now familiar underground vaults, with their white tiles, mosaic floor, and white glazed earthenware stalls. These conveniences, situated as far as possible on island sites in busy thoroughfares, took the place of old iron structures, with troughs and basins, which were always unsatisfactory and often foul. Since the nineties a great change has taken place in the social habits and conditions of the people of the metropolis, and this has made it necessary to review the existing provision and to determine its adequacy. During recent years an enormous number of women have entered the ranks of those who come daily from suburban to central London to pursue their occupation. The increase in road traffic and in facilities for public entertainment, and the habit of shopping at a distance, are all factors which lead to more people being away from home, and for longer periods, than formerly. For women, the present provision in central London is wholly inadequate, assisted though it is to some extent by special provision at restaurants, stores, and railway stations, the latter being preferred to the municipal provision on account of their greater privacy. Even for men the provision would be barely adequate were it not for a good deal of privately provided accommodation with access of a quasi-public character. In the outlying districts the public provision is very scanty; there it has been the custom to rely largely upon the accommodation which public-houses can offer, but the diminution in numbers of public-houses and the curtailment of opening hours has restricted this provision, which in any case was not very satisfactory. Dr. F. N. Kay Menzies, the medical officer of health to the Council, states that, apart from the great inadequacy of the provision for women, the principal need is for some improvement in directional indications to the whereabouts of the public conveniences; such directions should be as prominent as possible, while the accommodation itself should be inconspicuous. He adds some reference to the conditions in Continental capitals. In Berlin the construction of underground conveniences is now being pushed forward, and those above ground are being eliminated. In Paris by far the larger number of conveniences are above ground, and are used indiscriminately by men and

women; in the underground lavatories, numbering only thirteen at present, separate accommodation for the sexes is provided. In Rome there are only thirty-nine public lavatories, thirty-three of which are on the street level, but there is a good deal of semi-public accommodation at the restaurants and like places, and the same is true of Vienna, which has eighty-six public lavatories, of which only five are underground. In London the local authorities maintain 668 conveniences for men, 233 of them with w.c.'s, and the others with urinals only, and 184 conveniences for women. Dr. Menzies points out that while it would be ungracious to make comparisons where conditions are so different, yet the general standard of excellence of sanitation in London, the regard paid not only to decency but to delicacy of feeling, and the almost complete absence of gross nuisance, in spite of conditions of almost unparalleled intensity of occupation, constitute a civic achievement which no other city has surpassed. The London County Council is to give further consideration to the matter after the observations of the City corporation and the borough councils have been received.

The Cicely Northcote Trust.

The nineteenth annual report of the Cicely Northcote Trust, which was formed in 1909 to extend to the wards the social service work of the almoners' department at St. Thomas's Hospital, London, covers the year which ended last October, and again presents an interesting survey of varied activities. The expenditure of the trust was about £178 in excess of its income; this was due partly to expense upon repairs to the trust's hostel, but also to an increase in the work undertaken, which makes extended financial support desirable. The trust employs four almoners for social work in the wards, and the report contains convincing evidence of the value of this auxiliary service to that of the hospital proper. Advice and assistance are given on matters relating to insurance, compensation, convalescence, employment, and in many other ways less easily defined. The trust is also responsible for seeing that all insulin needed by patients is obtained, and undertakes the duty of ensuring the regular attendance of patients receiving this treatment. Another valuable activity is the after-care of cancer patients, in connexion with which efforts are made in appropriate circumstances to find suitable employment; the number of cases on the after-care register increased during the year to 1,289. It is intended in the course of time to extend the premises secured last year as a centre and club for fathers and mothers belonging to the St. Thomas's maternity department. In connexion with the International Social Service Conference held in Paris some months ago, the interesting fact emerged that when the hospital social service was started in Holland at the Wilhelmina Hospital in Amsterdam in 1913 it was modelled upon that of the Northcote Trust; similar services have since been instituted, following this example, in fifteen other hospitals in Dutch cities.

Correspondence.

A HINT TO MEDICAL TESTATORS.

SIR,—During 1928 I have seen in the press particulars of the wills of fully ten or a dozen medical practitioners who obviously, from the details given, had no dependants. Large sums were bequeathed to various deserving charities; but nothing at all to those charities which should have the first call on members of the profession—that is, Epsom College and the Royal Medical Benevolent Fund.

The bulk of us, of course, have to think first of our families when making a will; but to those who have none I urge the duty of preference to the proper charities of our own profession. At Epsom College the council are engaged on the uphill task of collecting money to build a new sanatorium. After a year and a half of effort about one-fifth of the large sum required has been obtained. A few good legacies would enable a start to be made with this most necessary improvement: *a fortiori*, from those who can afford them, immediate contributions of any size will be most gratefully accepted.—I am, etc.,

London, S.W.5, Dec. 30th, 1928. HENRY ROBINSON.

STANDARDS OF PUERPERAL MORBIDITY.

SIR,—All who are interested in obtaining reliable data regarding the frequency and distribution of puerperal sepsis and morbidity will agree with the Master of Rotunda when he says (*British Medical Journal*, December 22nd, 1928, p. 1155) that it is "most important that there should be absolute accuracy" in the standard of morbidity adopted. I should like, however, to point out that even if the standard of morbidity laid down by the British Medical Association is rigidly adhered to, reliable data will not necessarily be obtained. Puerperal morbidity is simply defined as a "rise of temperature to 100° F. or higher, on at least two occasions between the second and eighth days." But no instructions are given as to how the temperature is to be taken—whether in mouth or axilla. The same criticism applies to the standard of puerperal pyrexia laid down by the special subcommittee of the Royal Society of Medicine in 1925. It adopted the Strasbourg Convention standard which defined puerperal pyrexia as a "temperature of 100.4° F. (38° C.) or more, sustained during a period of twenty-four hours or recurring during that period."

Every ward sister knows that the mouth temperature is usually considerably higher than the temperature taken in the axilla. In order to test it, I took the temperature of a patient suffering from puerperal pyrexia. In the mouth the thermometer registered 100.4° F. after three minutes; after the same time in the axilla the same instrument registered 98.4° F.; this test was repeated with the same result. At University College Hospital all adult temperatures are taken in the mouth; at another large maternity hospital with which I am acquainted they are taken in the axilla. Obviously morbidity statistics from these two hospitals are quite incomparable. If unity in method of recording cannot be obtained it would be useful if a note were inserted in each hospital report stating definitely the standard of morbidity used and the method of recording adopted.

When the committee of the Royal Society of Medicine was sitting I wrote to the secretary drawing his attention to this point, but so far as I am aware no action was taken.—I am, etc.,

London, W.C.1, Dec. 28th, 1928. F. J. BROWNE.

STREPTOCOCCAL VACCINES FOR PUERPERAL SEPSIS.

SIR,—Dr. R. R. Armstrong and Mr. Wilfred Shaw, in your issue of December 15th, 1928 (p. 1082), draw from their work the conclusion that the prophylactic inoculation of streptococcus vaccine had failed, in their hands, to prevent puerperal infections. Does their investigation really justify that conclusion? In their summing-up at the end of the paper they assert that "morbidity in the puerperium is in the main due to a single cause, the *Streptococcus pyogenes*."

It will readily be seen that the validity of the conclusion about preventive inoculation really depends upon the truth of this latter statement; for, clearly, if there had been very little morbidity due to this streptococcus among the inoculated women, and much due to other causes, the benefit of preventive inoculation, directed specifically against this one microbe, would not be apparent in the morbidity rates. It may be well, then, to ask what is the evidence for the statement that *Streptococcus pyogenes* is the chief cause of morbidity in the puerperium. Dr. Armstrong and Mr. Shaw give us none—and so far as I know there is very little available. True, it is generally accepted—and I think quite rightly—that this microbe is responsible for most of the puerperal septicæmia and for most of the deaths; but it does not necessarily follow that the same holds true for the minor sepsis—the "morbidity"—of the puerperium.

During the past seven months an inquiry has been proceeding at Queen Charlotte's Hospital which throws some light on the matter. Almost every "morbid" and "clinically septic" case occurring in the hospital during this period has been bacteriologically investigated—by culture from the interior of the uterus, by examination and

cultivation of the urine, and, where there was high fever, from the blood also. The results up to date have been as follows:. 1,053 women have been delivered; 85 "morbid" and "clinically septic" cases of all degrees have been investigated—that is, practically all those in whom the febrile disturbance was judged to be due to infection arising from the genital or urinary tracts. Of these 85 cases only 6 have yielded a culture of *Streptococcus pyogenes*. In the remainder the predominant organisms recovered from cultures have been diphtheroid bacilli, *B. coli*, staphylococci, non-haemolytic streptococci, and various unidentified Gram-negative cocci and bacilli. The incidence of *Streptococcus pyogenes* infections may, then, be expressed as follows: 0.6 per cent. of the 1,053 women have developed morbidity associated with the presence of this microbe in the uterus; 7 per cent. of the group of "morbid" and "clinically septic" cases have been infected by it.

Possibly the investigation of a larger series will tend to raise these percentages somewhat. Meanwhile, it may be safely said that the figures fail to support the generalization of Dr. Armstrong and Mr. Shaw that *Streptococcus pyogenes* is the chief cause of morbidity in the puerperium; and they have, in consequence, an important bearing upon the statistical results presented by these authors. In the absence of evidence to the contrary, and in view of the fact that there was no epidemic in either series of cases, it would seem legitimate to assume that the incidence of infections by *Streptococcus pyogenes* among the St. Bartholomew's women was probably not greater than among those at Queen Charlotte's Hospital. (It may well have been a little less, owing to the fact that the Queen Charlotte's Hospital series almost certainly includes a larger proportion of difficult labours.) In that case, among the 668 women of the St. Bartholomew's series who received a prophylactic inoculation there would have been only four or five who might have been expected to develop morbidity due to infection by *Streptococcus pyogenes*. Surely in these circumstances there must be considerable doubt as to whether the determination of morbidity rates without bacteriological controls afforded a satisfactory basis for any conclusion. Any effect which the vaccination might have had could easily have been obscured by small fluctuations in the morbidity rate arising from causes other than infection by *Streptococcus pyogenes*.

Finally, I would submit that the same kind of criticism applies to the vaccine treatment employed by Dr. Armstrong and Mr. Shaw for the morbid cases of their second group. There must be considerable doubt as to how many of these cases were suffering from infection by *Streptococcus pyogenes*. Probably the majority were not.—I am, etc.,

London, W.2, Dec. 22nd, 1928. LEONARD COLEBROOK.

SIR,—I read the paper of Dr. Armstrong and Mr. Shaw (December 15th, 1928, p. 1082), and also Dr. Arkwright's comments thereon (December 29th, p. 1193), with much interest; but I should like to submit that the conclusion that vaccines have no therapeutic value in puerperal sepsis must be limited to the type of vaccine used in the investigation. It is now some years since I published a paper in the *British Medical Journal* upon two residual vaccines designed for use in acute infections, and I do not think that I am overstating the case for them when I say that they do not often fail to render the patient convalescent within twenty-four hours. This is not the place to describe them in any greater detail, but it should be said that they give rise to no sort of clinical reaction or shock: either the patient becomes rapidly well or remains exactly as if no vaccine had been given. It is now beginning to be recognized that the therapeutic action of a vaccine and the nature of the underlying mechanism of resistance is not nearly so simple as was formerly assumed. At the same time, I doubt if protein shock affords an adequate explanation; amongst a number of other reasons is the fact that these two vaccines produce their results with not the slightest trace of shock.—I am, etc.,

Manchester, Dec. 29th, 1928. C. E. JENKINS.

INVESTIGATION OF MATERNAL MORTALITY.

SIR,—The decision of the Maternal Mortality Committee to institute inquiries by public health officials into maternal deaths raises issues of great importance to general practitioners. We are told that the investigations are directed towards improving the maternity service of the country, but we are not told anything about the need for these investigations; we are not told what sort of information the Committee hopes to obtain that could not be obtained by other means, and we have not been asked whether we are willing to co-operate in this scheme.

General practitioners are as anxious as anyone to reduce maternal mortality, and I believe that they would not object to some form of consultation, with its traditional safeguards, to discuss a maternal death, but they object very strongly, I am sure, to any form of inquest.

To my mind there are grave objections to the Committee's scheme as it has been presented to practitioners:

1. The possibility of coercion. "I take it that if a doctor resents the inquiry he will say so." I quote an eminent public health official, and this, presumably, is the view taken by the Committee. The implication is clearly that if the doctor does not express his resentment the inquiry will be held. It is difficult to see what justification the Committee can have for acting on the assumption that if a doctor resents the inquiry he will say so, because it is obvious that the assumption may be mistaken and that such a mistake may be followed by very serious consequences. Let me put it in this way. A practitioner receives a letter to the effect that the county medical officer of health is directed by the Minister of Health to investigate the death of Mrs. X, and will be obliged if the practitioner will meet him. The doctor resents the inquiry, but, far from saying so, it never occurs to him to refuse to meet an official who comes down with all the prestige of the Minister of Health behind him. So that the investigator gets his information, but he gets it simply because the practitioner is overawed by his authority and feels compelled to speak. In my opinion an investigator who takes advantage of a feeling of compulsion to extract information is guilty of coercion, and whether he does so deliberately or unconsciously makes little difference to the victim. I submit that the bare possibility of coercion is intolerable, and especially so when this possibility can so easily be removed; all that is required is a second letter to practitioners asking them whether or no they are willing to have their cases investigated.

2. The answers to the following questions should have been made clear to practitioners:

> (*a*) Does the Maternal Mortality Committee propose to proceed with an investigation in which the doctor in attendance declines to collaborate? As the matter stands at present there is reason to believe that this is the intention of the Committee.
>
> (*b*) Is it clear that the investigator must not question relatives or nurses without first obtaining permission of the doctor in attendance?
>
> (*c*) Is it the intention of the Committee that its investigators should try to find out whether the disaster of a maternal death is attributable to lack of skill or care on the part of the practitioner or nurse?

3. The question of legal privilege is not made clear. In an explanatory note it is stated that information given on the inquiry form will be treated as strictly confidential. It is safe to say that a promise of secrecy signed by the Prime Minister himself would not induce a judge to go beyond established precedents in the matter of privilege, and that it would probably take an Act of Parliament to protect practitioners in the courts. In view of this difficulty practitioners may reasonably be asked to risk the question of "privilege," but if they do risk it it should be with their eyes open. It is very unlikely that the Committee would undertake to indemnify a practitioner who relied on its promise of secrecy and who had suffered in the courts in consequence. Perhaps one of the maternal welfare societies would agree to pay compensation. It is a possibility that might be explored.

4. There are other matters which are at present extremely unsatisfactory. One example must suffice. At the end of the inquiry form, after the space for the

comments of the doctor, there is a third space which gives the investigator the opportunity to add allegations which the doctor has no means of refuting.

I suggest, Sir, that the Maternal Mortality Committee should reconsider its decision, that a scheme with adequate safeguards should be worked out and submitted with full explanation of its scope and limitations to practitioners, and that practitioners should be asked to say whether or no they are willing to co-operate in the scheme submitted to them.—I am, etc.,

R. L. KITCHING.

Wetherby, Dec. 26th, 1928.

RADIUM AND CANCER.

SIR,—My attention has been drawn to a paragraph in the *Times* Weekly Edition of September 13th, 1928, headed "Radium and cancer," and quoting a statement by Mr. T. W. Paulin. In the course of this he refers to a "new technique" for the application of radium which has given most encouraging results.

> "The new technique, which has been in use on the Continent, at Brussels in particular, for some time past, consists in inserting a number of needles containing radium all round the cancerous growth . . . in favourable cases the growth is not only destroyed, but is prevented from spreading to the surrounding tissues."

This is perfectly correct, save for the statement that the technique referred to is new, and the inference that it was evolved on the Continent.

The technique was fully worked out here in Dublin, and has been in constant use for the last thirteen or fourteen years. The nature and theory of the technique were dealt with by the writer in a paper which appeared in the *Scientific Proceedings* of the Royal Dublin Society, May, 1914, p. 290 et seq., "On the local application of radium in therapeutics"; and evidence of its remarkable practical success appears in a paper contributed by Dr. Walter C. Stevenson to the *Dublin Journal of Medical Science* for March, 1915.

The following quotation from the latter paper shows that Dr. Stevenson was then quite cognizant of the value of boundary treatment as referred to in Mr. Paulin's statement. Dr. Stevenson is speaking of a case of cancer which, originating in malignant polypi of the nose, had, among other lesions, caused proptosis of the eye. With the object of inhibiting the growth from increasing upwards and pressing on the eyeball, Dr. Stevenson arranged a line of needles immediately under the orbit. His treatment had the desired effect. Dr. Stevenson adds: "This systematic radiation of a growing edge is only possible by the needle method, and is one of its great advantages." It is, therefore, evident that in every particular the technique Mr. Paulin refers to has been in use in this city since 1914 and 1915. So far as I know it originated and received its earliest trial and publication in connexion with the work done in the Radium Institute affiliated with the Royal Dublin Society.—I am, etc.,

J. JOLY, Sc.D., F.R.S.

Trinity College, Dublin, Dec. 18th, 1928.

THE INTERNATIONAL CANCER CONFERENCE.

SIR,—Our attention has been drawn to a statement—presumably a commentary on the recent Cancer Conference in London—by Dr. A. Leitch, which has been widely disseminated through the lay press. In this occurs the following remark: "Unfortunately the discussion failed to reveal much support for this particular mode of treatment [lead therapy], and it was unsparingly condemned by some of those in England and America who had given it a serious trial." As the result of this and other statements in the lay press we are expected by our patients and by their doctors to allay the fears which he and others have created in regard to our method of treatment. This can most properly be done in the medical press.

In the above quotation it will be noted that it is stated that our method was "unsparingly condemned by some of those . . . who had given it a serious trial." The so-called "serious trials" that led to the unfavourable opinions of which Dr. Leitch speaks must have been those mentioned in the report of the Cancer Committee of St. Bartholomew's Hospital, in that of the London Cancer Hospital with which Dr. Leitch is connected, and in the remarks of Dr. Burton Simpson of Buffalo, U.S.A.

At the Conference we treated the Bart's report more kindly than it deserved. We did, however, point out that it was hardly worthy of consideration for several reasons, one of which was sufficient to put it out of court—namely, that only twenty cases had been treated, and that of these fifteen were too ill to receive more than a very small, in some an infinitesimal, quantity of lead!

The remark made by Mr. Hume, who read the Bart's report, that the administration of lead converts the patients into "physical wrecks"—repeated in the press in headlines—was, we think, unfortunate, for it demonstrated only *his* inability to conduct the treatment properly. We are sure that if Mr. Hume could read some of the letters received from patients treated in Liverpool concerning the reports of his remarks as published in the lay press he would realize that he has still much to learn. We ourselves have observed no really serious reaction in any patient for some years. However, this report stood condemned by the illogical character of the evidence adduced.

With regard to the other report, that of the Cancer Hospital, the production of this at the Conference was a most unusual procedure, for the "observations" on which it was based had been published in the *British Medical Journal*[1] a short while previously—an action which could hardly fail to prejudice the discussion in advance. The interview granted to the lay press two or three days before the discussion by a member of that hospital staff, and the terms in which he then spoke of the treatment, must also have had a prejudicial effect.

It is, however, now necessary to recall what happened on the first publication of the report of the London Cancer Hospital, when it was severely handled by various correspondents in the *British Medical Journal*. Mr. Duncan Fitzwilliams wrote:[2] "From the results of this administration—I cannot call it investigation—Dr. Wyard [physician to the London Cancer Hospital] expresses an adverse opinion on the method of treatment by lead. It would be fairer, surely, if he had expressed an adverse opinion on his method of treatment by lead. Can any fair-minded or logical man say that anyone is justified in drawing conclusions from material such as this? I cannot think that even the most ardent opponents of the method . . . would care to quote such evidence."

We ourselves stated[3] that it was doubtful whether Dr. Wyard "ever seriously attempted to give the treatment a fair trial" at the London Cancer Hospital, and, among other criticisms, we demonstrated that Dr. Wyard had been lacking in "scientific and clinical acumen," and had drawn his conclusions "from this assembly of clinical and scientific errors."

With regard to Dr. Burton Simpson's remarks, although he spoke unfavourably of the method, it is interesting to note that in the report submitted he confesses that "all cases treated were in an advanced stage of the disease, and had previously been subjected to surgery or to radiation, or to both." Insufficient details are given to enable us to judge his methods of treatment, but he informs us of the terrible reactions from which his patients suffered. In support of his statements Dr. Simpson quotes Dr. Soiland, who treated thirty-one apparently similar cases and noted that "four are in good condition," and that in them the disease had been "apparently arrested"! Further, Dr. Simpson, with one of his colleagues (Dr. Marsh), had previously published[4] certain experimental work which was confirmatory of, rather than adverse to, our views.

Can these efforts be considered "serious trials," or must we simply regard them as the most serious work of which these authors are capable? The public, it seems, must be warned once more that the treatment is not only useless, but dangerous in unskilled hands. Professor Carter Wood of Columbia University, whose authority and caution in cancer research is undoubted, Dr. Loewy and Dr. Loiseleur of Paris, Professor W. Caspari of Frankfurt-a-M.

[1] *British Medical Journal*, 1926, i, 838.
[2] Ibid., 1926, i, 1017.
[3] Ibid., 1926, i, 958, 1087.
[4] *Journ. Cancer Research*, 1927, xi, 417

and Dr. A. P. Thomson of the Birmingham Cancer Committee gave encouraging reports. Others present, who had done a considerable amount of work on the subject, were prepared to speak in the same vein had the opportunity been given to them. As it was, we and many others left the meeting under the impression that a large majority was in sympathy with our work. This view has been confirmed by subsequent correspondence.

The refutation of ignorant criticism does not, of course, prove the value of the work condemned, and we would be the last to blind ourselves to this. Positive evidence alone can establish the promise of any effort. This we and other workers elsewhere have adduced, and, we hold, in a cautious manner. The following statement made by Professor Carter Wood at the Conference is surely the correct attitude of the really scientific man.

"It is evident from . . . carefully worded reports that the method is not at present one of general applicability, because of the high degree of clinical skill which is necessary for the proper treatment of patients and the dangers of the drug itself. Nevertheless, the fact that it is possible to cure even a relatively small number of otherwise hopeless patients is so important a discovery that every assistance should be offered . . . in the arduous work of ultimately defining the best practice of administration, in studying the method of action of the lead, and in attempting to improve the product." (Report of Cancer Conference, p. 204.)

In order that the profession may have more than fragments from which to judge, we hope in the spring to publish a volume in which our researches will be presented as fully as possible. Meanwhile, we would submit that the long-continued subversive attitude to our own work of Dr. Leitch, whose methods were so resented by the profession in 1926, is greatly to be deprecated, and should call for the serious consideration of all those who have the interests of cancer research at heart.—I am, etc.,

Liverpool, Dec. 19th, 1928. W. BLAIR BELL.

HEART SOUNDS.

SIR,—While heartily agreeing with Dr. Samways (December 8th, 1928, p. 1065) in his defence of the old-fashioned view as to the production of the heart sounds and also of the "pre-systolic" murmur, I feel that a word of physiological protest must be uttered with regard to his suggestion that, in spite of the absence of valves or adequate sphincter muscles, the auricle can develop a force comparable with that of the ventricle.

I think that before many more decades have passed the views expressed by Dr. Mayo Collier in 1889 in his able little book *The Physiology of the Vascular System* will have been generally accepted. This view was that the auricle is simply a reservoir from which the ventricle can fill itself during its very brief expansion phase (I believe it lasts only for one-tenth of a second).

The function of the appendix, however, is a more active one, for by a vigorous contraction it shoots a small quantity of blood through the closed (but not stretched) auriculo-ventricular valves into the ventricle, thus completing the filling of the ventricle and the stretching of its valves just prior to systole. As an addition to Dr. Collier's theory I believe that this sudden stretching of the heart muscles stimulates them to contract, and is, as it were, the spark which fires the powder.—I am, etc.,

Birmingham, Dec. 19th, 1928. T. STACEY WILSON.

DENTAL CARIES AND VITAMIN D.

SIR,—In his letter published on December 22nd, 1928 (p. 1155), Dr. J. Sim Wallace refers to some "essential facts" from which Mrs. Mellanby and Dr. Pattison's paper tends to divert our attention. So far as I can determine from the letter the "essential facts" seem to be: (1) that the addition of one ounce of bacon and half an ounce of cooking fat to a dietary will serve to retard caries; (2) that the addition of two ounces of sugar will serve to initiate caries. May I ask where one can find records that prove such implied statements to be facts? Why is sugar said to be more conducive to dental caries than any other carbohydrate? These, if facts, are vitally important, but one wants proof, not mere ex cathedra statements from an "authority." To prove these facts with proper controls must have involved great labour and care, comparable perhaps to the amount of labour and thought Mrs. Mellanby has given to her task.—I am, etc.,

Sheffield, Dec. 27th, 1928. A. E. BARNES.

SIR,—In your issue of December 15th, 1928 (p. 1079), you publish a paper by Mrs. Mellanby and Dr. Lee Pattison which, as you say in a leading article, is the latest of a long series relating to dental caries. The writers point out that their new group, A_3, has an average age of 5½, while the old (1926) Groups, A_2, B_2, C_2, are aged nearly 9, but they do not seem to attach much importance to the difference. They admit that the two groups are "not necessarily strictly comparable," but it does not seem to occur to them that some people might doubt if they were more than roughly comparable. Moreover, in a previous communication, they told us that Groups A_2, B_2, C_2 were all suffering from bone tuberculosis, but they do not think it worth while telling us whether the children of Group A_3 are suffering from the same disease. Are the children not necessarily strictly comparable in this respect as well?

The first thing that strikes one about the experiments themselves is that the duration is very short—about three months. This is roughly the shortest interval at which a dentist sees his small patients, and when he does see them so frequently he often finds that caries appears to be erratic. Some visits reveal several cavities, at others there are none. It is, of course, conceivable that the disease is intermittent, but a much more credible explanation is that diagnosis is erratic, while the disease is not. But if diagnosis of early caries is erratic even when performed by men who spend their lives using the mirror and probe, surely the writers are over-ambitious in trying to get comparative figures by the same means. To estimate the progress of caries may easily be more difficult still. The mouth of a cavity may remain unchanged for a short three months; does it follow that the inside of the cavity is also unchanged? Who, by looking at the outside of a tooth, can tell what is going on inside it?

I believe that the difficulties of the method used by the writers are so great that the results would have to be received with caution, even if the examinations had been made by dentists of experience and complete impartiality. Since writing the above I have seen Dr. Sim Wallace's letter. I confess I failed to detect the difference in diet which he has pointed out, but I entirely support his conclusions. The writers describe one adult patient, and she is almost a museum specimen, one of the fortunate few who, at the age of 22, are still unacquainted with the forceps or the dental engine. What one wants to know in a case like this is, not how much radiostol she had, but how she preserved her teeth for years before radiostol came. In any case, where twenty-nine teeth have taken care of themselves, the improvement in the remaining three is very doubtfully ascribed to radiostol.

It seems a pity that Mrs. Mellanby should spend her time on work of this inconclusive character, when, if her views are correct, a single set of experiments would go a long way to establish them. For if the inhibition of caries is due to pulp reaction, and this reaction is dependent on vitamin D, it should be a simple matter to produce caries experimentally, by giving a diet deficient in vitamin D to one group of animals, while a second group is kept caries-free on the same diet, *plus* the all-important vitamin. Why have not these experiments been made? Alternatively, if they have been made, why have not the results been published?—I am, etc.,

Oxford, Dec. 23rd, 1928. H. B. BARWISE.

ASTHMA RESEARCH COUNCIL.

SIR,—In March, 1928, I communicated to you and you were good enough to publish (March 17th, p. 468) the scheme of investigation and research which the Medical Advisory Committee proposed to carry out as, and when, the financial support of the Asthma Research Council permitted.

During the last nine months this committee has obtained the co-operation of many physicians in the provinces and

the consent of their local hospitals for the formation of research centres when these can be financed by the council. By means of grants made by the Halley Stewart Trust and the Medical Research Council, an asthma clinic and research centre has already been formed at Guy's Hospital to continue Dr. G. H. Oriel's investigation into the biochemical causation and treatment of asthma, and to supplement and control the results of such treatment by comparing them with those obtained by other methods. A second grant by the Halley Stewart Trust has been given for the study of the characteristics of asthma occurring in childhood; and a special clinic is now being organized at Great Ormond Street Hospital to carry out this work. A research fellow, endowed by the British Humane Association, has already visited many Continental spas, and is now investigating the results of the physico-therapy methods there employed by means of apparatus installed by that Association.

In order to obtain fuller statistics concerning hereditary influences on this disease and on the general asthma syndrome, family history forms have been approved and printed. They can be obtained from the medical secretary, and the medical advisory committee trusts that medical men who are interested in this subject will assist in circulating them among suitable asthmatic patients.

The Asthma Research Council itself, having meanwhile been strengthened and reorganized, will inaugurate a national appeal for funds at a Mansion House meeting at 3 p.m. on January 15th. The Lord Mayor will preside, and Sir Humphry Rolleston, Dr. Arthur F. Hurst, Colonel F. E. Fremantle, M.P., and Mr. Ben Tillett, among others, will speak. The attendance of medical men will be much appreciated.

The Council desires to raise a sum of £50,000; and donations should be forwarded to the honorary treasurer at the Council's office.—I am, etc.,

T. T. JEANS,
Surgeon Rear-Admiral (ret.),
Secretary,
Medical Advisory Committee.

Asthma Research Council,
42, Ranelagh Road, S.W.1,
Jan. 1st.

THE TREATMENT OF FEMORAL HERNIA.

SIR,—With regard to the letter from Mr. G. H. Colt in your issue of December 29th, 1928 (p. 1195), I beg to state that he will find that his queries were to some extent answered in an article on "The modern treatment of hernia" which I published in the *British Medical Journal* on January 27th, 1927. I there brought forward a comparatively large amount of evidence collected at the City of London Truss Society and at St. Bartholomew's Hospital, and tried to show (1) that femoral hernia recurred more often than was supposed after the "low operation" and after operations for the relief of strangulated hernia; (2) that the inguinal operation was efficient in a large series of patients with ordinary femoral hernia; (3) that a modification even of the inguinal operation was necessary in order to effect a cure in patients with large hernias—for example, with a wide neck to the sac, and with recurrences following the usual operation for strangulation.

After two years' further experience I have not found any reason for modifying the opinions which I then expressed.—I am, etc.,

GEOFFREY KEYNES.

London, N.W.1, Dec. 28th, 1928.

MENTAL HYGIENE.

SIR,—The leading article in your issue of December 29th, 1928 (p. 1183), raises many of the problems that demand research and solution if the standards of mental health of the community are to be raised. America, through its much more elaborate organization, has gone further than we have in these matters, and there are few who will not agree with you that enlightened public opinion is needed. If, however, we are to get this, is it not necessary that there shall be an enlightened medical opinion first of all? Better education in psycho-pathology and the treatment of early mental disorder is needed in the medical curriculum, but it would seem almost more important at the present moment that some effort should be made to give the general practitioners throughout the land some better guidance than they have yet had in dealing with these matters. Between the psychotic disorders and the illnesses of organic origin lie the psychoneuroses and the conduct abnormalities of children and adults. The general practitioner does his best with these conditions, which form a considerable part of his practice, but he has insufficient knowledge of them, and consequently is unable to make the best use of such modern theories and psycho-therapeutic methods as are of proved value.

A suggestion was made at the Psychiatric Section at the Cardiff Meeting this year, which was well received by general practitioners present, that the Association should take up this matter and aim at arranging a short course of lectures for every Division throughout the country. The management of the insane patient needs to be mentioned, but it is perhaps more the province of the general practitioner to deal with the psychoneurotic disorders, and it is to this primarily that attention should be directed. Mental deficiency, with its therapeutic and legal aspects, might advantageously be brought into the course. From the great interest that medical men as a whole take in investigating any new and useful method of treatment it seems improbable that there would be much difficulty in securing attendance at short courses of this sort, and there can surely be found in the various medical centres sufficient lecturers able and willing to undertake them. The Mental Hygiene Movement could receive no greater impetus than would be given by a movement of this sort on the part of the British Medical Association to institute post-graduate study of these problems from the therapeutic and preventive angles.—I am, etc.,

J. R. REES.

London, W.1, Dec. 30th, 1928.

SO-CALLED "WHITE ASPHYXIA" OF THE NEWBORN.

SIR,—Mr. Aleck Bourne's valuable letter in your issue of December 15th, 1928 (p. 1109), has been followed by communications which show clearly that the time is ripe for a general discussion on this important subject. It is probable that there would be a fairly wide acceptance of the view that the white baby is "shocked" rather than asphyxiated; but shock of the newborn is by no means identical with surgical shock of the adult, and the differences between the two conditions require to be defined as clearly as possible.

A discussion on this subject would not only help to clarify our views of a common and serious disability, but would serve to emphasize the need for more extensive investigations of foetal and neo-natal physiology, pathology, and pharmacology. Much has been done in recent years, but much remains to be accomplished.

Mr. Bourne has outlined his treatment of neo-natal shock, and it is probable that most clinicians would agree with him in general terms; but the actual details of treatment, including the use of lobeline, as well as the drugs mentioned by Mr. Bourne, would provoke a most helpful discussion in which obstetricians, paediatricians, and general practitioners could all join with advantage.—I am, etc.,

NORMAN B. CAPON, M.D., M.R.C.P.

Liverpool, Dec. 30th, 1928.

SIR,—Mr. Aleck Bourne, in writing a plea for abolishing artificial respiration for white asphyxia of the newborn, states of direct mouth-to-mouth insufflation, "Here nothing can happen but inflation of the stomach through the oesophagus." This, Sir, is surely too dogmatic an assertion. I can only state, equally dogmatically, that in the four cases in which I have used this method—other measures having failed—the lungs were inflated and natural respiration afterwards occurred. In one case this natural respiration was intermittent, and continued for some ten minutes only, when the child died; but in the other three cases healthy living children resulted. The method is unpleasant and, perhaps, not very safe for the operator; but I have no doubt whatever that, in many cases, it is the only hope for the child.—I am, etc.,

W. A. TRUMPER, M.R.C.S., L.R.C.P.

Devon, Dec. 21st, 1928.

TONSIL AND ADENOID OPERATIONS.

SIR,—I am in complete agreement with much of Mr. Tilley's contribution to this discussion (December 29th, 1928, p. 1194), but, while reluctant to differ from such an authority, I am still more reluctant to permit his advocacy of the routine application of ligatures in tonsillectomy to go unchallenged.

Experience and observation have demonstrated to me that such a procedure is not only unnecessary but also inadvisable. In the very great majority of tonsillectomies haemostasis occurs rapidly and conclusively without the application of ligatures. Moreover, in those cases where a ligature has been applied granulation tissue forms at the site of the ligature, healing is delayed, and ultimate scarring is more likely. These ill results are doubtless in part due to the inclusion in the ligature of other than purely vascular tissue, an occurrence which even with the greatest care cannot be altogether avoided.

In cases of tonsillectomy by the blunt guillotine the number requiring ligature is extremely small; in tonsillectomy by dissection—a method I reserve for adults and "recurrences"—I find that only about one case in twenty requires a ligature. This low figure is not obtained by any sacrifice of surgical principles, for no patient leaves the table bleeding, but by the occasional exercise of a little patience. In this connexion it may be noted that wool packed in the fossa is a very much more efficient haemostatic agent than the gauze mentioned by Mr. Tilley. If, when the fossae are empty and the pharyngeal reflexes are active, there is no bleeding, one can feel confident that there will be no reactionary haemorrhage.

Routine ligaturing must entail many unnecessary ligatures. Treatment of each case on its merits, with the application of a ligature only when necessary, results in so much speedier convalescence and so much better final results that any other course is to be deprecated.—I am, etc.,

Canterbury, Dec. 28th, 1928. THOMAS A. CLARKE.

SIR,—I wish to endorse strongly the remarks of Mr. Herbert Tilley in last week's *British Medical Journal* as regards haemorrhage in these operations. As one who also always employs the "dissection" method in private work I thoroughly agree with Mr. Tilley's insistence on the effective control of haemorrhage in the performance of the operation. Children do not bear haemorrhage well, and in those cases in which much loss takes place, either during or after operation, the child's health may be seriously affected for some weeks. No case should be considered finished and allowed to come round from the anaesthetic until both tonsil beds are dry, whether the case be that of an adult or a child; only in this way can post-tonsillar haemorrhage be reduced to a minimum. And though not always necessary in my experience in a child under 12 or 14, ligature of the vessels mentioned by Mr. Tilley is the only sure way of controlling them—occasionally other bleeding points, especially when close to the tongue, may also need ligature. Of course, I am not referring to those worrying cases, fortunately rare, when a general oozing persists or starts after operation, and where no ligature of any special point is of avail. In conclusion, I cordially agree with Mr. Tilley that we should emphasize most strongly the need for careful observation in these cases, and not consider as a light thing "the loss of a little blood."—I am, etc.,

Southsea, Dec. 30th, 1928. C. A. SCOTT RIDOUT.

CARDIOSPASM OR ACHALASIA OF THE CARDIA.

SIR,—The controversy between those who support these rival terms has been reopened in your columns by Mr. Greenwood's article in the issue of November 24th, 1928 (p. 932), and the replies of Dr. Hurst and Mr. Rake on December 15th (p. 1110). While disagreeing profoundly with many of Mr. Greenwood's statements and inferences, and while acknowledging that Dr. Hurst has introduced a most valuable method of treatment by means of mercury bougies, I cannot help feeling that neither name is entirely satisfactory. As Dr. Hurst is the originator and the principal exponent of the theory of achalasia of the cardia, I should like to ask him the following questions.

1. How does he explain the fact that the obstruction is not always at the cardia? With a typical history it may be in the middle of the oesophagus, and in one of my cases it varied in position—being at one time near the middle and at another time at the lower end. Would he regard these cases as spasmodic?

2. Does he think the comparison of the cardia with the anal sphincter is a satisfactory one, and would he seriously expect a spasmodic contraction of a sphincter like the cardia, which is so poorly developed that some authorities have even denied its existence, to grip the mercury tube as an anal sphincter in spasm will grip the finger?

3. Does he consider that in cases of achalasia of the cardia there is always a residue of eight inches of food in the oesophagus? Has every eight-inch column of food the same weight, and has every cardia exactly the same resistance to relaxation?

4. If the answers to question 3 are in the affirmative, what happens in the cases occurring in small children? The youngest of my patients was only 4 years old, and an eight-inch column of food would have overflowed into the pharynx.

5. If the cardia relaxes when the column of food exceeds eight inches, why does it close again as soon as the height falls once more to the exact level of eight inches? Once it has relaxed, why does not the relaxation persist until the whole column has fallen through?

I should also like to ask Mr. Rake whether he really meant that the wall of the oesophagus was 4 cm. thick at the upper end in his first case. Incidentally I may mention that the average thickness of the muscle at the cardia in his twenty normal cases slightly exceeds that found in a series of 123 cases measured for me by Drs. Woods and Bratton at the London Hospital, the average in these being just under 0.25 cm.—I am, etc.,

London, W.1, Dec. 31st, 1928. C. C. BEATTY.

PAPULAR URTICARIA.

SIR,—I am very pleased to learn that Dr. G. H. Lancashire proposes to admit to hospital one of the patients he supposes to be sensitized to a food protein, and I hope he will have the kindness to inform me should the characteristic lesions of papular urticaria follow the ingestion of the particular protein. I should then be convinced that one of the exciting causes of this peculiar complaint of infants is a food sensitization.—I am, etc.,

Sheffield, Dec. 31st, 1928. RUPERT HALLAM.

"THE RIGHT TO PRACTISE."

SIR,—In reply to Dr. A. G. Newell's letter (December 29th, 1928, p. 1197) may I refer him to the words of the Medical Act of 1858, Section 34?

"After the 1st day of January, 1859, the words 'legally qualified medical practitioner' or 'duly qualified medical practitioner,' or any words importing a person recognized by law as a medical practitioner or member of the medical profession, when used in any Act of Parliament, shall be construed to mean a person registered under this Act."

Anyone, therefore, who is not registered under the Act is not a "duly qualified medical practitioner," and has no "right" to practise as such.—I am, etc.,

Hyde, Cheshire, Dec. 28th, 1928. J. GORDON MACQUEEN.

SIR,—Surely Dr. A. G. Newell has also confused himself about the "rights" of this question. I refer to the concluding sentence of his letter, in which he illustrates the position of a man whose name has been removed from the *Medical Register*, and states, ". . . he still possesses the legal right to practise *provided* his university or other qualifying body has not taken away his degree or diploma." The proviso governing this statement is entirely misleading. Even if every degree or diploma was taken away the man in question would still

be free to practise medicine and/or surgery with impunity. Such is the law as it stands, and it is well that the issue should be clearly stated and understood.—I am, etc.,

Tunbridge Wells, Dec. 31st, 1928. W. E. HEMPSON.

SECURITY OF TENURE IN PUBLIC POSTS.

SIR,—I have been asked, as the writer of the first letter on the above subject, to make some remarks on the letters that followed. The consequences of insecurity are so widespread that any discussion must traverse regions apparently foreign to the subject. I can only deal at present, therefore, with the general aspects presented.

Readers will have noticed that whereas the two writers who acquiesced in the *status quo* signed their letters, three of the four who criticized it did so anonymously; a course doubtless distasteful, but thought necessary because of insecurity in their posts. One may suppose this feeling stifles in others also that frank expression of opinion so necessary for progress in any field of endeavour. A medical contributor to a contemporary, who abstracted my letter into its columns, stresses this point.

Under the present state of insecurity large bodies of doctors engaged in work of the utmost importance to the community are perforce inarticulate. They cannot unite in defence of their interests or betterment of their position. This is a grave situation which the British Medical Association cannot continue indefinitely to ignore. The importance of their work is known to all. Taking a minor branch mentioned in several of the letters—namely, the asylums, we find there are over 130,000 mental patients in public institutions in England and Wales alone. There are roughly 100 public asylums, with probably 450 doctors employed, of whom say 350 are subordinate and inarticulate. £8,000,000 of public money is spent annually on these asylums, the entire administration of which is deputed to the medical superintendents. Since each superintendent starts as an assistant medical officer, the training, habits of mind, and traditions of the subordinate medical staffs are essential factors in the welfare of the service as well as of their patients. Moreover, from the medical superintendents are chosen the medical members of the Board of Control—the official advisers of the Government in all that concerns the mentally ill of the nation.

"M.B." sees a connexion between insecure tenure and the rather low status of the assistant medical officer. This is a reflection on a devoted body of brethren working under conditions that smother initiative and professional enthusiasm. But there are grounds for his assertion. Again, taking the asylum doctors as a test, we find that the qualifications and records of original work possessed by the average medical superintendent do not compare with those of his "opposite numbers," the specialists of the big general hospitals. British alienism has not brought forth a Lister or a Jenner; if we would meet their compeers we must go to Austria, to France, to Germany, to Italy. It is a disturbing thought that inspires the question "Have we been rearing our young asylum doctors on the correct lines"? Even if we apply the test to the members of the central body itself we find (with one praiseworthy exception) little to suggest eminence. With regret we fail to find the D.P.M. attached to a single name. This, the simplest specialistic qualification in psychiatry, should be compulsory for every doctor in charge of the insane. It corresponds to the D.P.H., compulsory for years past on medical officers of health. Insecurity of tenure and the evils arising from it, cause promising men to avoid these national services. But the State has a claim to the best brains in the profession, and the conditions should be such as will attract them. How sad it is they fell into the hands of petty parochial bodies, and thus lost all co-ordination!

The Association may regard the subject from the standpoint of the material prosperity and comfort of the medical man, or with the more altruistic objective of the national health. In either case it has here the chance of performing a great work by raising the status of these services. As a first step let it take legal advice, and draw up a provisional form of agreement ensuring adequate security of tenure to every pensionable doctor. Then let it enforce this by refusing advertisements from authorities who decline to conform.

The greatest evil of the present position is that secret charges, which he has no means of discovering, and which result in the instant loss of his post and pension, can be made against a doctor. This may occur even if he has served more than the statutory number of years necessary to entitle to a pension. He is removed by "termination of the appointment," which is not "dismissal" in law; thus he can take no steps to defend his good name and professional reputation. This should be made impossible. The known existence of this Cheka-like machinery of repression, even if never used, is harmful alike to management and staff of an institution. It is easy to show that it is antiquated and father to a multitude of evils, and when this is done the case for a move on to a system more in consonance with the spirit of the times and the dignity of our profession is practically completed.—I am, etc.,

Wedmore, Dec. 2nd, 1928. H. C. MCMANUS.

Universities and Colleges.

UNIVERSITY OF OXFORD.

THE following candidates have been approved at the examination indicated:

FINAL B.M., B.CH.—(*Medicine, Surgery, and Midwifery*): A. R. Bowtell, S. B. Davis, R. M. J. Harper, A. G. Hill, R. G. Macbeth, D. C. Shields, Margaret A. L. Herbertson, Joyce Wr[illegible]: P. M. F. Bishop, J. F. Brock, J. M. L. [illegible] W. J. Cotton, R. F. Lomax, R. L. H. [illegible] A. H. Bateman, F. Bell, J. F. Brock, J. L. Clapham, A. Guirdham, M. A. Hatt, J. C. Leedham-Green, W. H. McMenemey, J. C. Neely, J. N. O'Reilly, R. S. B. Pearson, B. T. Squires, Anne D. M. Adams, Olive M. Capper-Johnson, Amy C. E. Clarke, Victoria M. Robinson. (*Forensic Medicine and Hygiene*): H. R. J. Donald, J. A. Eddy, R. G. Macbeth, H. E. Mansell, J. C. Neely, J. C. Nicholson, G. P. Roxburgh, W. J. Walter, H. G. Wells, Ruth Sandeman.

UNIVERSITY OF CAPETOWN.

Graduation Ceremony.

AT the December graduation ceremony of the University of Capetown the following were admitted to the degree of Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.):

M. J. Cohen, G. J. Conradie, J. C. Downes, S. W. Jaffe, B.A., S. Kahn, B.A., P. Kushlick, L. J. J. Muller, W. H. Opie, D. H. Pfeiffer, R. B. Saunders, B.A., S. Schur, B.A., R. Turner.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

SURGERY.—E. A. Johnstone, E. A. *Lipkin*, D. M. Nightingale, A. K. Rama Chandra, R. W. Scanlon.

MEDICINE.—W. S. Ghai, D. H. Haler, K. R. Lundeberg, K. G. Milad, T. A. P. Proctor, A. K. Rama Chandra, H. Tenenbaum.

FORENSIC MEDICINE.—W. S. Ghai, D. H. Haler, C. K. McCoan, J. H. McGibbon, K. G. Milad, T. M. White.

MIDWIFERY.—W. D. Glynn-Jones, D. H. Haler, K. G. Milad, B. J. Niall, K. M. Seedat, T. M. White.

The diploma of the Society has been granted to Messrs. W. S Ghai, E. A. Johnstone, W. D. Glynn-Jones, E. A. *Lipkin* K. R. Lundeberg, A. K. Rama Chandra, K. G. Milad, T. A. P *Proctor, H. Tenenbaum*

Obituary.

WILLIAM THORNBOROUGH HAYWARD, C.M.G., LL.D., M.R.C.S., L.R.C.P.I.,

Consulting Physician to the Adelaide Hospital, and Consulting Medical Officer to the Adelaide Children's Hospital.

WE have to record with great regret the death, at the age of 73, of Dr. W. T. Hayward, which took place on December 21st, 1928, at Adelaide, Australia.

William Thornborough Hayward was born at Reading on January 26th, 1854. He received his early education at St. John's College, Hurstpierpoint, proceeding to his medical studies at the Liverpool School of Medicine in 1869, where he became silver medallist in medicine, surgery, and pathology. In 1873, after gaining an exhibition at the Liverpool Royal Infirmary, he became an assistant to a general practitioner, qualifying L.R.C.P.I. and L.M. in 1874. In the following year, having in the interim made two visits to South America as ship surgeon, he became house-surgeon to Mr. Bickersteth, one of the earliest disciples of Lister, and was able to observe the development of aseptic surgery. During his term of office he assisted in the application of Thomas's splints, the first used in any general hospital, and became an enthusiastic exponent of the value of this surgical appliance. Indeed, a few months later, when he was appointed house-surgeon to the Liverpool Children's Hospital, he was successful in introducing this method of treatment for cases of hip and knee disease. Some years later, in 1883, he exhibited Thomas's splints at a meeting of the South Australian Branch of the British Medical Association, probably the first occasion on which the subject had been brought before a medical society in Australia.

DR. WILLIAM T. HAYWARD.

In 1877 Hayward again served as ship surgeon, and arriving at Adelaide in 1878 he settled down in private practice. He was elected honorary physician to the Adelaide Hospital in 1885, and continued to hold this appointment until 1914, when he was appointed honorary consulting physician. Between the years 1889 and 1899 he was honorary medical officer to the Adelaide Children's Hospital, being appointed honorary consulting medical officer on his retirement. Eight years after his arrival in Australia he was appointed lecturer in clinical medicine at Adelaide University, holding this office till 1914, and lecturer in materia medica and therapeutics from 1888 to 1920. He was appointed a member of the council of Adelaide University in 1899, a position he held until 1924. He represented the university on the board of management of Adelaide Hospital.

During the great war he was on active service with the Australian Forces, being gazetted major in the Army Medical Corps in 1915, lieutenant-colonel later in the same year, and colonel in 1918. He was employed on headquarters staff until 1915, when he was appointed officer commanding 1st A.A.H. Harefield. In September, 1917, he was transferred to Boulogne, where he was appointed senior physician to the 2nd Australian General Hospital, a position he held till 1918, when he became senior medical officer of the review board. He was mentioned in dispatches in 1917, and a year later received the honour of C.M.G.

Dr. Hayward was an active and enthusiastic member of the British Medical Association, and in 1879 he was in large measure responsible for the formation of the South Australian Branch, the first Branch of the Association in Australia. He became its vice-president in 1884, and was elected president in 1885. From that time onwards he held a number of important offices, representing his Branch on the Australasian Federal Committee from 1911 to 1922, and serving as a member of council for twenty-seven years. In 1912 he was elected first chairman of the Federal Committee, holding this office till 1922, and from 1914 to 1918 he was a member of Council in London for South Australia and Victoria, being elected a vice-president of the Association in 1914. The Federal Committee of the British Medical Association, Australia, presented him in 1914 with the gold medal of honour "for distinguished service." He was the first recipient of this medal in Australia. In 1914, on the occasion of the British Medical Association's Annual Meeting at Aberdeen, the University conferred on him the honorary degree of LL.D. This recognition of Dr. Hayward's merits gave great pleasure to his friends, and he himself took a legitimate pride in what he regarded as an honour not merely to him as an individual but to Australian medicine. In the same year he became an honorary LL.D. of the University of Adelaide.

As a physician Dr. Hayward held strong views, which he was always ready to convey with courage and conviction. In 1898 he brought the subject of pleural empyema before the profession in Australia. He strongly advocated the view that practically all cases of this disease in children were due to the pneumococcus, the so-called pus being broken-down fibrinous exudate which could be evacuated by rib resection. He recorded cases which showed that by this means drainage could be completed in twenty-four hours. He was an enthusiastic exponent of venesection in selected cases, and did a great deal to introduce its use to the notice of his colleagues in Australia. Convinced that the overfeeding of invalids was the cause of many troubles usually attributed to the disease from which they were suffering, he made a practice of greatly restricting the diet of his patients, of even forbidding food at certain periods, and gained thereby the name of "the starving-doctor." He believed that alcohol had been given far too important a place in therapeutics, and in the last decade of his practice at Adelaide Hospital he hardly ever prescribed it. His bedside teaching and lectures on therapeutics had a considerable influence in reducing the prescribing of alcohol in Australia. He was the author of a number of clinical papers in the *Australian Medical Gazette*.

During his stay in England Dr. Hayward made many personal friends, who will feel his loss keenly. By his death Australia has lost a public-spirited citizen and a fine physician and teacher, and the British Medical Association a devoted worker and a loyal colleague.

DAWSON TURNER, M.D., F.R.C.P.ED.,

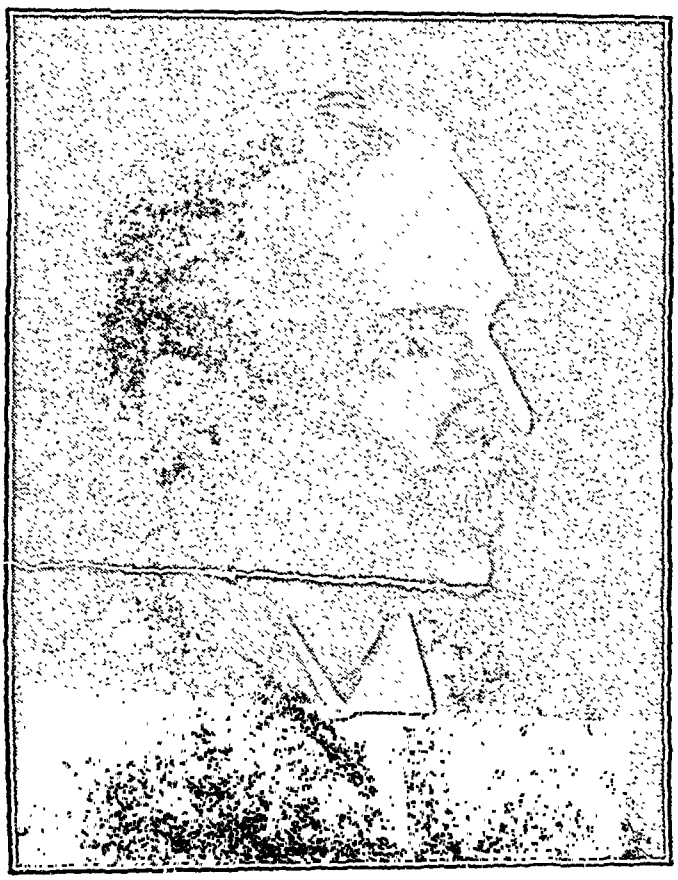
Honorary Consulting Physician in Radiology, Royal Infirmary, Edinburgh.

WE have to announce with deep regret the death of Dr. Dawson Turner, one of the pioneers in radiology in Edinburgh, which occurred on December 25th, 1928, at Godalming, Surrey, where he had been living since his retirement a few years ago.

Dawson Fyers Duckworth Turner was born at Liverpool in 1857, and after graduating B.A. at Dalhousie University, Canada, went, in 1884, to Edinburgh to study medicine. He graduated M.B., C.M. with honours in 1888, proceeding M.D. in 1890. In the same year he obtained the diploma M.R.C.P.Ed., being admitted to the Fellowship in 1891, and became also M.R.C.P.Lond. During the summer of 1889 he acted as resident physician in the Royal Infirmary with Sir James Affleck, having as fellow residents Dr. R. A. Fleming, Professor Robert Muir, the late Professor James Ritchie, and Mr. Alexander Miles, and was later house-physician in the Royal Maternity and Simpson Memorial Hospital. After a period spent in visiting foreign schools of medicine, he turned his attention to lecturing on physics in Surgeons' Hall, Edinburgh, being also clinical tutor in the extramural class of clinical medicine. Shortly after he had begun to lecture upon physics the *x* rays were discovered by Roentgen in 1895, and Dawson Turner was one of the first to recognize their possibilities in medicine. A primitive *x*-ray installation, which was the first in Edinburgh, was set up in his house at George Square, and attracted much attention when he demonstrated to his friends and colleagues its properties of showing up bones and foreign bodies in the tissues. When, a few years later, radium was discovered, he soon secured a specimen, to which he added from time to time. For many years this was the only supply of radium in Edinburgh, and Dr. Turner generously placed it at the disposal of the Royal Infirmary for the treatment of patients until the managers secured supplies for the institution. It was natural that when an *x*-ray department was installed in the Infirmary it should be placed under his charge, and although his health determined him a few years later to abandon the management of the radiological department, he retained his connexion with it as honorary consulting physician in radiology to the Infirmary, and for many years continued in charge of the treatment by means of radium. In common with many of the early workers in radiotherapeutics, Dr. Turner suffered considerable deterioration in general health from the ill effect of long exposure to the rays, which was in the early days of radiology little understood. He lost successively three fingers and an eye from this cause, and the effect of these losses on his general health led to a considerable curtailment of his activities.

In addition to his lectureship in physics, Dr. Turner acted as examiner in physics in the Royal College of Physicians of Edinburgh, and additional examiner in physics in Edinburgh University, and he was for a time vice-president of the Roentgen Society. His *Manual of Practical Medical Electricity* was a well-known textbook on this subject for many years, and went into a fourth edition, while his smaller work *Radium, its Physics and Therapeutics* was also widely used. He contributed many papers, mostly on physical subjects related to medicine, to various medical journals, such as an article on "The haemorenal salt index and deficiency of the kidney," published in the *Transactions of the British Association* in 1906, and an article on "Electrolysis in medicine and surgery" contributed to the *Edinburgh Medical Journal* in 1908. In that year, at the Annual Meeting of the British Medical Association at Sheffield, he was vice-president of the Electrical Section.

Apart from the affairs of his profession, Dr. Turner had many interests. He was an accomplished linguist, had travelled much, and possessed wide general culture. He was one of the earliest men in the medical profession to take up motoring in the closing years of last century, and enthusiastically recommended this means of progression as a method of applying open-air treatment in cases of phthisis. Although, for reasons of health, he had retired from medical work in Edinburgh and had sought a home in the South of England, he maintained communication with many friends in Edinburgh, by whom, as well as by the public bodies with which he was connected, his loss will be keenly felt. He is survived by a widow.



DR. DAWSON TURNER.

Dr. JOHN W. L. SPENCE, radiologist, Royal Edinburgh Hospital for Sick Children and Deaconess Hospital, writes:

Nearly thirty years have passed since I was asked by Dawson Turner to assist him in the newly organized X-Ray Department of the Edinburgh Infirmary. It then consisted of two rooms, well below the street level, and with a precipitous wooden stairway leading to it. From the very start Turner displayed the keen interest and masterly powers of arrangement which characterized all he did. He did much for radiology and later in the domain of radium. He was gifted with excellent observation and forethought. To his pioneer labours and wide outlook are largely due the present well-equipped radiological department of our Infirmary. Possessing a retiring and reserved disposition he did not make friends readily, but, hidden by this reserve, one found a staunch and loyal fellow worker. He was the soul of honour and carried with him an old-world courtesy—rare in his generation. His achievements have been an impetus to the progress of medicine, and his name will endure on the scroll of time. Those who knew him best will cherish the memory of an indefatigable student and worker, untarnished by selfishness and petty jealousy.

His researches, at a time when the evil effects of *x* rays were unknown, led to years of suffering, which undermined his strength and in the end killed him. Through it all he bore his sorrows and losses with a great fortitude and courage. Of Dawson Turner it may well be said, in the heroic endeavour to save human life, he serves God best who most nobly serves humanity.

[The photograph reproduced above is by the Central Press.]

PETER BROOME GILES, C.B., F.R.C.S.Ed.,
Colonel A.M.S.(T.).

We regret to announce the death on December 19th, 1928, at Folkestone, after a long illness, of Colonel Peter Broome Giles, who was prominently associated with the medical service of the old Volunteers, and later with that of the Territorial Force, and was long recognized as an authority on ambulance work.

He was born on April 5th, 1850, the eldest son of Peter Broome Giles of Staunton-on-Wye. His school days were passed at St. Catherine's Hermitage, Bath, kept by William Horner, son of the mathematician. From there he went to study medicine at University College, London, and obtained the M.R.C.S.Eng. diploma in 1871, the L.R.C.P.Ed. in 1872, and the L.S.A. in 1876. In 1897 he became F.R.C.S.Ed. After holding a succession of house appointments at University College Hospital he returned to the West of England, combining the work of a general practitioner with active participation in the Volunteer and ambulance movements and the enjoyment of country sports. He was a good shot, a keen fisherman, and for a number of seasons acted as Master of the Herefordshire Staghounds.

After many years of practice at Brobury, near Hereford, Broome Giles moved to Buckinghamshire, where he kept up his interest in all sides of public life. Having served on the magistrates' bench in Herefordshire, he was made a justice of the peace for the county of Buckingham, and in later life, after retirement from active medical work, he became justice of the peace for Folkestone. In 1906 he was elected to the Buckingham County Council, and served in the following year as high sheriff. Before leaving Wye-side he rose to be brigade-surgeon lieutenant-colonel of the 1st Herefordshire R.V. and Welsh Border Volunteer Infantry Brigade, and surgeon lieutenant-colonel in the Army Medical Reserve. He was made county director of the City of London Branch of the British Red Cross Society in 1905, and on the formation of the Territorial Force he became A.D.M.S. of the 1st London Division, with the rank of colonel. He received the Volunteer and Territorial decorations, and in 1911 was created C.B. The war gave him opportunities for employment in further army medical work. He was appointed commandant of the military convalescent hospital at Alnwick in 1915, and of that at Ashton-in-Makerfield in 1917, and served later upon a Pensions Board.

Colonel Broome Giles was an old member of the British Medical Association, and held office as chairman of the Aylesbury Division in 1905. In the following year he became a member of the Volunteer Medical Service Committee appointed by the Council to consider the question of reorganization; he attended the meetings regularly and took an active part in the committee's work until the issue of its report in 1907. He was the author of several books on the training of stretcher-bearers, and of papers on ambulance work and the organization of military medical units; and from time to time letters from his pen appeared in our columns. All that he wrote was in keeping with his vigorous open-air personality.

Colonel R. R. Sleman, M.D., writes: Peter Broome Giles commenced his military career in the ranks of the Artists' Rifles; when qualified he took a commission as surgeon in the Herefordshire Rifles, later being promoted to the rank of brigade surgeon in the Welsh Border Brigade. In this capacity he solved the difficult problem of the formation of Volunteer brigade bearer companies—namely, he enrolled the Welsh Border bearer company on the strength of one battalion. He rendered great assistance to the Army Medical Department before the formation of the Territorial Force, during which time, as commandant of the Volunteer Ambulance School of Instruction, he had had great experience in the teaching of Volunteer medical officers, and the regimental stretcher-bearers of the London district. When he was commandant of the Military Convalescent Hospital at Ashton-in-Makerfield during the great war he was severely injured in an air raid. A man of good physique, always enthusiastic and optimistic, he was much liked, and was a good judge of man or horse.

F. W. TUNNICLIFFE, M.D., M.R.C.P.,
Physician, King's College Hospital, London; Lecturer on Therapeutics, King's College Hospital Medical School.

We record with regret the death of Dr. Francis Whittaker *Tunnicliffe*, which occurred at his residence in Harley Street, on December 15th, 1928, at the age of 62. He was *the youngest* son of the late Frederick Warner Tunnicliffe, and was born at Blana, Eccleshall, Staffordshire. He received his medical education at St. Bartholomew's Hospital, where, after serving as house-surgeon, he came greatly under the influence of Sir Lauder Brunton. Hence his interest in the subject of pharmacology. After leaving St. Bartholomew's Hospital he studied in Vienna and Prague, and later was appointed to a position at King's College, where he was for some time professor of materia medica and pharmacology. He became physician to King's College Hospital, and lectured on therapeutics and the practice of medicine at the medical school.

Dr. Tunnicliffe was appointed a member of the departmental committee on preservatives and colouring matter in food; he examined in materia medica at the Royal College of Physicians; he was a member of the Medico-Legal Society, and a fellow of the Royal Society of Medicine. At one time he was physician to the North London Hospital for Diseases of the Chest. His contributions to medical literature consisted of papers on the physiology and pathology of the respiratory, circulatory, and digestive organs; and ranged from an article, with Sir Lauder Brunton, on the effect of massage on the circulation to observations on the effects produced in the human organism by such substances as piperidine, boric acid, formic aldehyde, and phosphorus compounds. Dr. Tunnicliffe served on the former Therapeutic Committee of the British Medical Association, and was secretary of the Section of Pharmacology at the Annual Meeting at Manchester in 1902. Owing to his devotion to a subject which, however useful, is not generally considered attractive by medical men, he was not perhaps as widely known as many consultants of his standing. But in that subject he had achieved for himself a position of prominence.

PETER MAURY DEAS, M.B., M.S.,
Formerly Medical Superintendent, Wonford House Hospital, Exeter.

We regret to have to record the death of Dr. P. M. Deas, which occurred at his home at Budleigh Salterton, Devon, on December 15th, 1928, at the age of 86. He had spent the larger part of his active life in mental hospital work, and at one time took a prominent part in the affairs of the British Medical Association, of which he was a member for over forty years.

Peter Maury Deas received his medical education in the University of Edinburgh and in Paris. In 1863 he obtained the diploma L.R.C.S.Ed., and graduated M.B. and M.S.Lond. in the years 1865 and 1866. In the course of his undergraduate career he won several scholarships and exhibitions, and a gold medal in forensic medicine at the University of London. He was for some time assistant physician at the Royal Edinburgh Asylum, and was later medical superintendent of the Cheshire County Asylum, ultimately being appointed medical superintendent of the Wonford House Hospital for the Insane at Exeter in succession to Dr. Sutherland Rees Philipps, who resigned the post on his appointment as medical superintendent at Virginia Water. Dr. Deas held office at Wonford House for twenty-five years. When he went there the establishment was still seriously hampered by a large debt, which had been incurred to move the hospital from its first situation in the lower part of the city and to build a new establishment on the present healthy site. He brought the institution safely throughout these difficulties, and enabled it to buy much of the surrounding land, which, with the present extension of suburban building in Exeter, is of great value. The most notable feature of his tenure of office was the high administrative capacity which he exhibited. The minutes show that he really reorganized the institution, and both he and Mrs. Deas displayed the greatest energy in the administration and in looking after the comfort of the inmates. He was the author of a number of contributions to medical journals on subjects

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

DRY SKIN

DR. E. C. MUDIE (Glasgow) writes: In reply to "H. M. C." (December 15th, 1928, p. 1120) may I suggest that, in addition to the administration of thyroid extract (or a mixed gland preparation), he should prescribe general tonic treatment, together with local erythema doses of the quartz mercury vapour lamp? In my own practice the Jesionek, with the quadrilateral reflector, is used for the body bath at three to five feet, while the Kromayer is most useful for the localizing of treatment in which a third degree erythema should be produced. I generally give treatment thrice weekly at first, gradually diminishing the frequency to one a week.

PTYALISM IN PARALYSIS AGITANS.

DR. E. J. JENKINS (Hunstanton) writes: I should be grateful if any of your readers could suggest a way of relieving excessive salivation in a man of 60, who is suffering from paralysis agitans. The saliva runs down his chin continuously, and is a source of much irritation. It is possible that some kind of pastille, sucked in between his meals, might relieve this annoyance, but I should like to hear first if anyone else has successfully treated this local condition *without interfering with the normal flow required for meals.*

TREATMENT OF MEMBRANOUS COLITIS.

DR. G. WILLETT (Keynsham) writes: In answer to "Country Doctor's" query as to the treatment of membranous colitis (December 29th, 1928, p. 1202), may I quote my experience of a similar case. I was reading up its literature and was much struck by this sentence—"When in doubt use your microscope, and make certain you are not dealing with a dysentery." I took the hint, and, finding the *Amœba hystolytica*, was fortunate enough to bring about a rapid recovery by using emetine hypodermically, followed by a short course of pills (salol covered) of emetine-bismuth-iodide 3 grains daily for twelve days.

MUSCULAR CRAMPS IN ARTHRITIS.

"ALPHA" writes: A married woman, aged 76, who is a victim of arthritis, is much troubled by muscular cramps at night. She was quite free during an attack of lobar pneumonia and for some weeks after. Can anyone suggest a remedy, or report the results given by luminal in such a case?

INCOME TAX.

Appointment and Locumtenent Expenses.

"P. L." holds a public appointment on condition that absence from any cause other than her own illness or the statutory holidays shall be provided for by the engagement of a locumtenent at our correspondent's own expense. The inspector of taxes objects to the deduction of such expenses incurred during the serious illness of "P. L.'s" father.

*** The inspector appears to be technically correct. The expenses which can be deducted are those incurred wholly, exclusively, and necessarily in the performance of the duties of the office. The expenses in question were undeniably incurred in order that for the period concerned "P. L." might be free from the performance of her duties. The alternative contention is that the contract between "P. L." and the local authority was for the performance of certain work by herself or another, and that as it is open to her to do the work or find a substitute at her own option the expense incurred by the latter method is not allowable. We fear, however, that the former view is sounder. With regard to the subscriptions paid, the amounts can be deducted as expenses, provided that membership of the societies or associations concerned is a condition of employment under the agreement with the local authority.

LETTERS, NOTES, ETC.

MIRROR-WRITING.

DR. A. A. E. NEWTH (Attenborough) writes: Referring to the subject of mirror-writing, your readers may be interested to know that a year or two ago I met an officer in the Royal Engineers who possessed the faculty. With his right hand he wrote ordinary [illegible] with his left hand he produced, equally [illegible] which on examination before a looking-glass, was found to resemble closely the forward writing of the right hand, so that one would have no hesitation in saying that the two were written by the same person. Writing backwards with the right hand, or forward with the left, was as laborious to him as it would be to a normal individual. He could read the mirror-writing of his left hand no more easily than a normal person, and so found difficulty in correcting what he had written, although he could feel in an instant when he made an obvious mistake. In sketching the human face he was accustomed to draw with his right hand when the subject was looking to the *left*, and with his *left* hand when he or she was looking to the right. He was right-handed in some games, left-handed in others. He had discovered his faculty for mirror-writing when, as a small boy he had injured his right wrist, and so had to write temporarily with his left hand. He developed his newly discovered accomplishment in order to amuse his fellows. Later in life, having to sit for an examination, he had the misfortune to injure his right hand again, and he obtained permission to write his paper with his left hand—mirror-writing.

DR. EVA MCCALL (London, W.1) writes: Two cases of mirror writing recently came under my notice in the infant department of a large L.C.C. elementary school. The children were between the ages of 5 and 6, and neither showed any evidence of mental deficiency. One case was obstinate, and all efforts on the part of the teacher to correct the mirror-writing (which was typical and extended to numerals) were in vain. The child, however, suffered from defective vision and squint. As soon as the parents could be prevailed upon to have this defect treated by suitable glasses she at once began to write normally, and has continued to do so since. The other case was one of a single aberration, due to excitement; neither before nor since has she written in this way.

EXAMINATION VAGOTONIA.

DR. C. FRASER BROCKINGTON (Leicester), in the course of a letter dealing with the mental paralysis which assails some candidates during the oral examination, writes. Vagotonia may not be the sole cause, but it is the cause of the worst degrees of "viva palsy." Such vagotonics normally exhibit sinus arrhythmia, have a pulse of 60, and in times of mental stress they sweat abnormally, experience inertia, and suffer from looseness of the bowel. There is a long latent period between the acception of the sensory stimulus and the resultant motor activity. As a result these candidates appear dull and stupid. When they are questioned they are seized with panic and feel they must answer something, even if it be the first available thought. Only too often they answer incorrectly. Perhaps these neurotics would be helped immensely by the knowledge that examiners were aware of their condition.

PHLEBITIS.

MR. A. P. BERTWISTLE, F.R.C.S.Ed. (Harrow), writes: I am much interested in the letter of "M.D." on December 15th, 1928 (p. 1112); a well-recorded personal case, as Paget showed admirably, is of infinite value. His phlebitis bears many points in common to one I reported in the *British Journal of Surgery* 1928 (p. 275). If, as appears *not improbable*, the lymphatics become infected, there is a grave danger of elephantiasis developing. I should like to know whether he has had his teeth x-rayed. If he has any dead ones I should recommend their extraction, as a radiogram may, at times, fail to reveal infection. I do not think that any staphylococcal vaccine or serum is of service in these cases, though antistreptococcal serum is of definite value for this and many other conditions.

A WARNING.

A CORRESPONDENT informs us that a person representing himself to be Dr. E. S. Duffy, of Oldbury Road, Smethwick, Birmingham (who died on September 11th, 1928), called upon a medical practitioner in London recently and obtained the loan of a sum of money, after stating that he had left his pocket-book at home. It is also stated that this person has been ordering goods at various London shops in the name of the late Dr. Duffy. We understand that the matter has been reported to the police, but medical practitioners will do well to be on their guard against persons who approach them in this manner.

VACANCIES.

NOTIFICATIONS of [illegible] vacant in universities, medical colleges, and at hospitals, with [illegible] and of vacant resi[illegible] our advertisement columns, be found at pages [illegible] ps, assistantshi and locumtenencies at pages 54 and 55.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 7.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

1. Chronic Fatigue Toxaemia.

M. GOLOB (*Med. Journ. and Record*, November 21st, 1928, p. 503) considers that chronic fatigue toxaemia is a definite morbid entity, which is too often overlooked or confused with organic disease presenting similar symptoms. Physiologists have fully recognized the importance of fatigue; animal experiments have revealed the harmful effect of undue exercise on the nervous system, and the existence in the blood of exhausted animals of definite fatigue-producing substances. Golob states that fatigue is unquestionably associated with the retention of and saturation with certain substances, among which are creatin, sarcolactic acid, monopotassium phosphate, and carbon dioxide. Imperfect removal of waste products, insufficient supply of oxygen, and poor nutrition are contributory factors in the production of these fatigue substances. Rest has been proved to be the physiological antidote to fatigue; it is of primary importance in the treatment of pulmonary tuberculosis; and anorexia may be a defensive symptom in disease, as it heralds the approaching malady and gives the digestive apparatus the needed rest beforehand. Golob classifies fatigue into acute and chronic. The former is divided into physiological fatigue arising from over-exertion, and symptomatic fatigue preceding the invasion of an infectious disease. Chronic fatigue is divided into basic fatigue, a symptom of organic disease, such as exophthalmic goitre, and essential fatigue or chronic fatigue exhaustion, without discernible organic pathology. The last-named type is chiefly dealt with in this paper. Mimicry of symptoms is characteristic of essential fatigue. Because of heightened sensitiveness to stimulation it may simulate other maladies, either of environmental or endogenous origin. Persons in all walks of life and of all ages are susceptible to fatigue intoxication. The institution of rest pauses in workshops, offices, and schools will assure more efficient work and better health. Complete rest and relaxation is the most logical treatment for chronic fatigue intoxication; diet and medication have only a secondary role, if any at all, in the treatment.

2. Pancreatitis following Mumps.

P. MERKLEN and H. GOUNELLE (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, November 15th, 1928, p. 1490) report a case of pancreatitis as a sequel to mumps. A woman, aged 23, suffered for a fortnight from gastric pain and diarrhoea; the pain was violent and constant, the point of maximum intensity being in the middle of the left hypochondrium. Nausea and occasional vomiting were present; food, especially meat and fat, increased the pain. Palpation only revealed acute tenderness over a point between the epigastrium and left hypochondrium. The patient gave a history of having had a swelling in the left parotid region, accompanied by slight pain. This attack preceded the other symptoms by a few days. The stools were liquid and contained much undigested material, together with muscular fibres; there were no fat droplets, but many crystals of amino-acids were seen. The urine contained no sugar or acetone bodies, but after salol had been given salicylic acid was found. The blood showed a rise of glycaemia to 1.41 grams. A strict vegetarian diet, without any other treatment, cured the diarrhoea in five or six days, though the pain continued for nine days. At the same time the glycaemia fell to 1.28 grams. After one more week the patient was discharged, without pain and with a good appetite; she began to eat meat, and the stools remained normal. During the next four months the patient had three attacks of pain and diarrhoea although on a vegetarian diet; the glycaemia figure was 1.24 grams, but there was no glucose in the urine. The authors report this case as being intermediary between the curable diabetes which may develop after mumps and severe diabetes with a glycaemia of 3.27 grams and coma. The case was one of early diabetes, and showed that glycaemia might be the sole biological manifestation of disordered pancreatic mechanism caused by an initial parotitis.

3. Gastric Dysfunction in Disseminated Sclerosis.

L. HESS and J. FALTITSCHEK (*Med. Klinik*, October 5th, 1928, p. 1538) have investigated the motor and secretory functions of the stomach by *x*-ray screening and Ewald's test meal in a number of cases of disseminated sclerosis in which there was no pain, tenderness, or other evidence of coincident gastric disease. They found that in each case there was hypermotility with diminished emptying time; in 20 out of 21 cases described in detail the stomach emptied in twenty to forty minutes, only one taking as long as seventy-five minutes. The acidity of the gastric contents, as compared with 1,200 other test meals, gave a high normal value in about half the cases, the rest showing hyperacidity. They also record that accelerated emptying has been found to occur in thoracic herpes zoster and post-encephalitic Parkinsonism, and mention cases recorded by others in which spinal caries was associated with disturbed gastric function, apparently produced by pressure interference in the spinal cord with fibres from the sympathetic ganglia. The authors contend that if a pathological process produces either irritation or interruption of the vagal or sympathetic nerve fibres or centres the motility of the viscera supplied is likely to suffer; the onset of disseminated sclerosis is often characterized by the early occurrence of parasympathetic disturbances in the innervation of the bladder, eye, and larynx. They have observed that extreme constipation, previously absent, was a frequent early symptom of disseminated sclerosis, and some observers have recorded such gastric symptoms as vomiting of the cerebral type. Hess and Faltitschek therefore consider it not unlikely that with the scattered distribution of lesions which occurs in disseminated sclerosis, sclerotic patches affecting areas controlling visceral innervation might produce the gastric hypermotility and hyperacidity which they have observed as well as the other autonomic nervous symptoms mentioned; they also suggest as an interesting point in the pathogenesis of this disease that vagal hypertonia may be a predisposing factor.

4. Cardiac Dyspnoea.

F. R. FRASER (*Med. Journ. of Australia*, October 20th, 1928, p. 491) classifies the causes of dyspnoea into chemical and nervous groups. The first group comprises alterations in oxygen and carbon dioxide pressure and in hydrogen-ion concentration. Such factors may operate singly or combined, according to the predominance of circulatory, pulmonary, or renal disease. An investigation of the blood gases in hyperpnoea due to mitral stenosis revealed no relevant changes in the arterial blood except in advanced cardiac failure, so that hyperpnoea in uncomplicated cases must be due to stagnation of blood and anoxaemia of the tissues, particularly those of the respiratory centre. Engorgement of the lungs with blood occurs in congestive heart failure and produces diminished vital capacity with dyspnoea. In the later stages of failure gross oedema of the lungs and hydrothorax must increase this effect, while shallow breathing may itself induce anoxaemia. The vital capacity is also dependent upon posture, being reduced in the prone position; hence the appearance of orthopnoea in advanced cardiac failure. For the occurrence of periodic breathing there must be oxygen lack at the respiratory centre and also capacity for considerable increase in pulmonary ventilation, so that rapid elimination of carbon dioxide and consequent apnoea may be produced. The reduction of vital capacity in congestive failure makes increased ventilation impossible, so that periodic breathing is rare in this type of failure. The paroxysmal attacks of dyspnoea typical of failure, with hypertension and myocardial degeneration, are believed by many to result from hyperpnoea and resulting engorgement of the right side of the heart and the lungs. Morphine, by quieting the respiratory movements, is of great benefit in this form of paroxysmal dyspnoea, but oxygen should be simultaneously administered to counteract the anoxaemia which may result.

5. Serum Immunization against Measles.

N. S. FERRY, E. J. GORDON, F. W. MUNRO, A. H. STEELE, and L. W. FISHER (*Journ. Amer. Med. Assoc.*, October 27th, 1928, p. 1277) report the clinical results obtained with a toxin procured from a streptococcus isolated from patients suffering from measles which was associated with the particular antitoxin. From 10 to 20 c.cm. doses of the serum were used, since it was found that 5 c.cm. doses were not sufficient to protect against measles. In hospital, where those treated with 20 c.cm. of antitoxin were controlled under similar conditions with an equal number of untreated persons, the actual protection was 88 per cent. In another hospital, where patients treated with 10 c.cm. of antitoxin were controlled with a larger number of untreated patients and with a larger number treated with 5 c.cm. of measles convalescent serum, the protection afforded by the antitoxin was 42 per cent., as compared with 19 per cent. in the case of those treated with

convalescent serum; at a convalescent home, where the susceptible patients were selected according to their reaction to measles toxin, the actual protection was 67 per cent. From the three series of cases in the three institutions the average computed actual protection was 66 per cent., and where the dose was 20 c.cm. it was 78 per cent. The fact that in thirteen out of thirteen cases (100 per cent.) at the convalescent home it was shown that infection and recovery from measles changed a positive skin reactor to measles toxin to a negative reactor, and that diluted measles convalescent serum neutralized measles toxin, is held to indicate a specific relationship of measles toxin prepared from *Strep. morbilli* to measles, and to favour the use of streptococcus antitoxin prepared from this toxin as a protective measure.

6. Lactic Acid Excretion during Exercise.

I. SNAPPER and A. GRÜNBAUM (*Nederl. Tijdschr. v. Geneesk.*, November 3rd, 1928, p. 5419) summarize their observations on 55 football players as follows. Before the game only a trace of lactic acid was found in the urine; after the game not more than a trace of albumin was detected, and in one instance glucose was present. In games played on warm days only 6 of the 55 players showed more than 60 mg. of lactic acid in the urine. On the other hand, in two games played on cold days the urine of 13 players showed more than 60 mg. of lactic acid. In view of the fact that the same player excretes less lactic acid on warm days than on cold days, it is deduced that during work lactic acid leaves the body in considerable quantities by other channels than the urine; large quantities of dextro-rotatory lactic acid have been found in the sweat. During a game of football lasting one and a half hours in sunny weather an average of from 1.1 to 2.2 grams of lactic acid was excreted in the sweat, and in some cases presumably more. At the onset of perspiration the sweat contained more lactic acid than at the termination of the process. It is suggested that the phenomenon of "second wind" may be partly connected with excretion of lactic acid by the sweat.

7. Alcoholism and Cancer.

J. FLAIG (*Med. Welt*, November 17th, 1928, p. 1704) alludes to the Medical Research Council report which showed that the incidence of cancer of the tongue and oesophagus was unusually high in those employed in the drink trade, whereas in occupations with an unusually low cancer mortality there was a corresponding low mortality from diseases due to alcoholism. American statistics in 1916, which could be regarded as a normal pre-war and pre-prohibition year, showed that the incidence of cancer of the alimentary tract went hand-in-hand with a high mortality from alcoholism and cirrhosis of the liver. Thus, the mortality per 100,000 inhabitants from alcoholism and cancer in prohibition States was 2.7 and 75.7 respectively, as compared with 5.6 and 83.5 in States with a partial licence, and 9.0 and 81.7 in those with a full licence.

Surgery.

8. Haemostatic Artificial Pneumothorax.

P. COURMONT and H. GARDÈRE (*Journ. de Méd. de Lyon*, October 20th, 1928, p. 581) recommend artificial pneumothorax as being the best method of arresting haemoptysis when this endangers the patient's life or has resisted ordinary treatment. Haemorrhage ceases usually after one or two insufflations, even when the pneumothorax is incomplete. In some very urgent cases it is necessary to insufflate immediately; in others repeated haemorrhages indicate the necessity for compression by an artificial pneumothorax. The authors record twelve cases in their own practice in which haemostatic pneumothorax was induced. They state that usually the results are excellent, both as regards the haemorrhage and as favouring healing of the tuberculous lesion. The technique of the operation is similar to that of ordinary pneumothorax. The gas employed may be oxygen, nitrogen, or ordinary air; nitrogen furnishes the most prolonged compression, while oxygen is absorbed most quickly; air is employed in urgent cases in the absence of other gases. An instrument fitted with a manometer must be used, and a guarded safety needle is recommended. When the haemoptysis is alarming, insufflation should be more rapid than in an ordinary pneumothorax. The quantity of gas required is much greater than in ordinary cases, and the compression should be higher. The authors have almost always used more than one litre, and sometimes as much as 2.5 litres in certain cases. Generally speaking, when there are no pleuritic adhesions a large amount of gas is required to produce a positive pressure. The insufflations are repeated frequently as in ordinary pneumothorax: sometimes this is necessary every day or on alternate days in order to maintain a positive pressure. In exceptional cases it has been performed twice a day. The authors have never seen any ill result. In some cases haemoptysis was arrested despite extensive pleuritic adhesions which prevented complete pulmonary collapse; a remarkable fall in temperature and a rapid improvement in the general condition have often been observed. In adults the age of the patient is not a matter of importance.

9. Benign Tumours of the Stomach.

J. T. MASON and M. F. DWYER (*Annals of Surgery*, November, 1928, p. 866) report three cases of benign tumours of the stomach which occurred out of four thousand cases examined clinically and by x rays. These tumours, though rare, may be the cause of an aty [illegible] complaint or an unexplained chronic [illegible] commonly called polyposis. In each case there was a lack of gastric symptoms; weakness, anaemia, and loss of weight were present, and diarrhoea was very persistent in one case, but none of the patients attributed their ill health to a lesion in the stomach. The tumours were diagnosed by means of x-ray examinations, and were located on the posterior wall of the stomach. The operative technique is simple, a small transverse incision being made in an avascular surface of the stomach, the incision being gently enlarged to three times its size by the use of small retractors. In approaching the tumours haemostats were applied to the base, being attached well on the side of healthy mucous membrane. The tumours were then removed and the actual cautery was applied to the base above the haemostat and held on the blade of this until the instrument had received enough heat to coagulate the tissues and blood vessels to the immediate tissues. The grasping area of the haemostat was then whipped over with a running suture of double dulox, and was slipped out of place before the suture was pulled taut. Over this approximation several interrupted wax sutures were placed. Convalescence in each case was uneventful.

10. ACCORDING to A. A. STRAUSS, J. MEYER, and A. BLOOM (*Amer. Journ. Med. Sci.*, November, 1928, p. 631), though gastric polyposis occurs rather infrequently, routine radiography has of recent years drawn attention to this condition, the most important of the benign gastric tumours. Several theories have been advanced as to the little-known causative factors of the disease; among these are heredity, chronic gastritis, a general systemic lymphatic hypertrophy, and metabolic changes. It occurs usually after middle age, and the sexes are equally affected. Menetrier's classification of these tumours, which is still accepted, is into polyadenoma polyposa and polyadenoma en nappe. The latter type is rare; only five cases have been reported in the literature, and the authors now report two more such cases. In the first group the ducts are principally involved, the tumour is more lobulated, and cysts are more common; in the second, usually located in the fundus, there is little lobulation, cysts are few or absent, and the hypertrophy forms a well-demarcated plaque. Gastric polyposis may exist for many years without causing any discomfort, though the symptoms may be very severe in some cases, depending on the size, location, and nature of the growth. The chief symptoms are chronic gastric discomfort, repeated gastric haemorrhages, nausea, achylia, abnormal amounts of gastric mucus of egg-white consistency, and increased or normal gastric motility, combined with a general appearance of well-being. Physical signs are usually absent, and the most marked finding is the x-ray picture, which shows a characteristic mottling at the site of the lesion. The diagnostic problem is its differentiation from chronic gastric ulcer, carcinoma, sarcoma, and syphilis. Complications which may arise during the course of the disease are prolapse of a pedunculated tumour into the pyloric opening, associated carcinoma, and carcinomatous degeneration of the tumour. Improvement has been noted in a few cases from x-ray and radium therapy. Most cases have been treated by radical operation, and, where the extent of involvement permits, gastric resection according to Polya's method is advised. The authors emphasize the necessity of careful clinical and radiological interpretation in order to eliminate malignancy.

11. Treatment of Haemorrhoids.

H. GARIN (*Journ. Med. Assoc. of South Africa*, October 27th, 1928, p. 549) emphasizes the importance of careful selection of haemorrhoid cases for operation. Many patients may be relieved, if not cured, by simple dietetic or medical measures; others require more active treatment on account of repeated attacks of inflammation, serious bleeding, or discomfort. Operations on neurotic patients are often disappointing, pain or discomfort persisting after apparent cure. In elderly patients who have arterio-sclerosis or hypertension serious cerebral trouble often develops within a few months

after operation. It is useless to operate on haemorrhoids when these are due to hepatic cirrhosis or intrapelvic tumours. Excision of the pile-bearing area is not without risk, even when performed by experienced surgeons. Garin considers the injection treatment of haemorrhoids to be safer than any other surgical procedure. He prefers the older treatment (80 per cent. phenol glycerin) under local (or preferably general) anaesthesia. A fine needle, 1½ inches long, is attached to the syringe filled with solution; it is wiped (to prevent any solution touching the skin) and inserted into the skin at a third or half an inch from the anal margin. With the left index finger in the rectum the needle is thrust into the centre of each pile, only one or two drops of solution being injected. After each injection the needle is withdrawn sufficiently to permit slight lateral movement, so that as many piles as possible are injected without withdrawing the needle from the skin. Usually two skin punctures suffice. If the piles are large it may be necessary to inject at four equidistant points around the anal margin. When the needle is withdrawn the region is irrigated or washed with alcohol to remove any trace of phenol. The exposure of the whole area outside the anus prevents sloughing of the subjacent tissues. When every nodule has been injected, vaseline or an antiseptic ointment is applied. The piles are left outside, and a small rectal tube is inserted. The patient remains in bed for three or four days. An aperient and an oil enema are given. In five or six days the sphincter recovers its tone. Warm Sitz baths aid the contraction of the piles, and in two weeks small nodules only remain. Very cold enemata relieve any congestion of the mucous membrane. Relapses seldom occur if patients ensure regular actions of the bowels. Pelvic thrombosis or embolism has never been recorded.

12. The Surgical Significance of the Abdominal Reflexes.

W. KLEIN (*Arch. of Surg.*, November, 1928, p. 854) considers that the cutaneous abdominal reflexes are a valuable aid in the diagnosis of acute intra-abdominal disease. These responses are of two kinds: (1) hyperaesthesia, which is a form of hyperalgesia and is defined as a response to a stimulus expressed in terms of pain; (2) the contraction reflex, which is a response to scratching of the skin over a particular area. Klein thinks that the second one has not received sufficient attention. Hyperaesthesia, which is of value in diagnosing conditions in adults, is present early in the course of abdominal disease in about 50 per cent. of cases, and diminishes later; any process which causes increased tension, increased peristalsis, or acute inflammation will give the sensation of increased pain when the skin over the affected area is pinched. The cutaneous contraction reflex, which is helpful in diagnosing disease in young persons, is produced by scratching the skin with a sharp object. It is seen as a homolateral, segmental contraction of the muscular segment at the site of stimulation. The linea alba and the umbilicus deviate to the same side. This contraction occurs almost simultaneously. Rigidity of the abdominal wall which is not the result of an intra-abdominal condition may be accompanied by an exaggerated contraction reflex, while that caused by the inflammation of the peritoneum results in the disappearance of this reflex. The degree of suppression is in direct ratio to the severity of the pathological process; the area of absence of this reflex overlies the diseased organ. When the peritonitis is diffuse the whole abdominal wall is non-responsive. Both reflexes are unilateral and segmental.

13. Phagedaenic Destruction of the Male Genitalia.

J. H. LABADIE (*Journ. Amer. Med. Assoc.*, November 10th, 1928, p. 1447) records seven cases treated during the last twelve years in the Michigan University Clinic of Dermatology and Syphilology of phagedaenic ulceration complicating genital lesions. The clinical course was essentially the same in all, varying only in degree. The cases were characterized by chronic painful destructive ulcers which began on the prepuce, glans, or sulcus coronarius, and spread by direct extension back along the shaft of the penis. In the severest cases the scrotum and even the abdominal wall were involved. The disease begins with a chancroidal infection, often complicated by chancre, and secondarily infected with the usual saprophytes of the skin. Untimely surgical intervention such as a dorsal slit, a circumcision, or local incision and drainage is perhaps the most important causative factor present, since this serves to open up new avenues for infection and aids in the implantation of the saprophytic organisms deep into the healthy tissue. Histologically the picture is that of a non-specific chronic inflammation. The cases are very refractory to all forms of treatment. Free drainage as provided by baths, irrigation, and frequent soaking is imperative. In severe cases the actual cautery or even amputation of the part may be needed.

Therapeutics.

14. Treatment of Rickets.

WHILE irradiated sterols have proved of undoubted benefit in experimental rickets in rats and in infantile rickets, E. LESNÉ, R. CLÉMENT, and S. SIMON (*Bull. et Mem. Soc. Méd. des Hôp. de Paris*, November 22nd, 1928, p. 1525) state that their therapeutic efficacy is affected by such factors as the age of the child, environment, diet, duration of the disease, and the degree of the lesions. Cure is more rapid if the patient dwells in airy, well-lighted surroundings, has a normal diet, and is not suffering from advanced lesions. Irradiated sterols have no greater effect than other medicaments on well-established osseous lesions. The authors report good results from the administration of daily doses of 4 mg. of ergosterol, one of the best results being from a daily dose of 1 mg. during two periods of five days each with an interval of a month without treatment. Ergosterols recently irradiated are said to have a striking anti achitic activity. The majority contain from 25,000 to 100,000 physiological units of antirachitic factor per gram, this unit being the amount necessary to protect a rat of the weight of 30 grams against the effects of a rachitigenous diet. A child with developing rickets should receive daily for a month about 100 units of antirachitic factor, which corresponds to 1 to 4 mg. of ergosterol correctly and recently irradiated; such ergosterols lose almost all their efficacy at the end of three months. Though certainly efficacious in rickets, they should not replace in all cases actinotherapy or cod-liver oil. Ultraviolet rays have as rapid an effect as ergosterols, and, moreover, are accompanied by a more marked eutrophic action, stimulation of appetite, and amelioration of the anaemia. Cod-liver oil contains 90 units of factor D per c.cm. It is very rich in the lipo-soluble factor of growth, of which irradiated ergosterols are totally devoid, and its fats are particularly assimilable. Flaudin has called attention to the difference between ergosterin and cholesterin: the first has a marked antirachitic power; the second possesses this in a lesser degree, but its action on growth is more obvious, and it has also an antitoxic and anti-infectious property. Preparations containing both these substances are said to produce better results than ergosterin alone, and to approximate those due to cod-liver oil, which is not always tolerated.

15. Stramonium in Parkinsonian States.

SOPHIE SHAPIRO (*Journ. of Nerv. and Ment. Dis.*, November, 1928, p. 488) calls attention to Juster's method of treating Parkinsonian symptoms by the oral administration of *Datura stramonium*. Increasing amounts of the dry leaves are given, beginning with 1-grain doses three times a day until 14 to 16 grains daily are being given. As soon as the optimal result is obtained the dose is decreased until 7 or 8 grains daily is reached. One day of intermission is allowed after five or six days of treatment. No evil effects have been reported. Twenty-three cases are described (16 of Parkinsonism and 7 of classical paralysis agitans). The results in 14 cases (11 Parkinsonism and 3 paralysis agitans) are said to have been excellent, and in 9 cases there was slow improvement. The majority consisted of post-encephalitis lethargica patients, in whom more improvement was noticed in both physical and mental condition. Chief among the signs improved by treatment were muscular rigidity, excessive salivation, posture, speech, and mental condition. Some previously bedridden patients were enabled to get up and dress themselves, intelligible articulation returned, the gait became more steady, and the mental outlook more normal and hopeful. It is said that prolonged dosage sometimes causes diarrhoea and mydriasis, but these effects vanish when the administration is stopped for a day or two. Aged people with considerable arterio-sclerosis and severe tremor show comparatively slight improvement. The author claims merely symptomatic and perhaps temporary relief, but adds that the absence of danger in administration, and the return from complete or partial invalidism to a more normal, useful, or pleasant life, make treatment by stramonium worthy of serious consideration.

16. Colloidal Mercury in General Paralysis.

M. PINARD, P. VERNIER, and Mlle VERSINI (*Bull. et Mém. Soc. Med. des Hôp. de Paris*, November 1st, 1928, p. 1456) report the case of a man who had suffered from general paralysis since 1925. He was at first treated with injections of novarsenobenzol, and subsequently with intramuscular injections of bismuth and quinine. Some slight improvement followed this treatment, but the Wassermann reaction remained positive. In spite of seven courses of novarsenobenzol the Wassermann reaction continued positive and his general condition was but little better, so in July, 1928, a course of intraspinal injections of colloid mercury in 2 c.cm.

doses was started. In August the Wassermann reaction was found to be negative, and he was then given a 5 c.cm. dose of colloid mercury, which produced a violent reaction. At the conclusion of treatment the patient's general condition had much improved and the Wassermann reaction remained negative. The severe reaction which occasionally followed the mercurial injections were combated by injections of morphine.

17. Theophylline-Ethylenediamine in Heart Disease.

J. H. MUSSER (*Journ. Amer. Med. Assoc.*, October 27th, 1928, p. 1242) discusses the use of theophylline-ethylenediamine in the treatment of cardiac disorders associated with pain. The preparation has been in general use as a diuretic, especially in congestive heart failure; it acts as a dilator of the coronary arteries to a greater degree than any other member of the xanthine group. In heart conditions with anginal attacks, in cardiac failure in conjunction with digitalis, and in hypertensive heart disease associated with cardiac pain it acts favourably by dilating the coronary arteries, increasing the circulatory rate, and allowing a greater supply of blood to reach the myocardium; it is also of use in cardiac dyspnœa and asthma, cases of heart-block, and in aortitis and coronary sclerosis. Its greatest value is seen in the treatment of angina pectoris or in patients who have survived the initial effect of coronary thrombosis. While it is difficult to estimate the action of a drug when given in conjunction with other measures to restore compensation, the author's experience, like that of others, is that patients with comparable signs and symptoms of cardiac failure of the congestive type improve more rapidly and completely with combined digitalis, theophylline-ethylenediamine therapy, and rest in bed than do those under the same conditions but without theophylline-ethylenediamine. F. M. SMITH (ibid., p. 1274) emphasizes the importance of combined dieting and theophylline in the treatment of cardiac failure. Attention is called to the beneficial action of the carbohydrates and sugars upon the injury to the liver produced by prolonged congestive failure, and to the value of the drug in doses of 2 or 3 grains after meals in the treatment of the failure due to arterio-sclerosis. The best results are obtained in the congestive type of failure and in fluid elimination from its influence on the coronary circulation.

18. Splenic Extract in Pulmonary Tuberculosis.

BAYLE (*Presse Méd.*, December 8th, 1928, p. 1563) has obtained good results from the administration of splenic extract in advanced cases of pulmonary tuberculosis in which pneumothorax was impossible, and in others where single or bilateral pneumothorax had failed to arrest the course of the disease. He employs an extract of pig's spleen unmixed with the extract of any other organs, and administers it by the mouth, by hypodermic injection, or by both methods when desirable, the usual length of treatment being three weeks. Twenty-two cases are recorded in which the treatment has been employed over various periods, and they are classified as follows: (1) splenic treatment alone without previous pneumothorax—5 cases, good results in all of them; (2) splenic treatment alone after pneumothorax had been abandoned—2 cases, one able to resume games, the other much improved; (3) splenic treatment accompanying pneumothorax, then alone—4 cases, in which the general condition was improved in 2 and the response was excellent in 2; (4) splenic treatment concurrent with pneumothorax—6 cases, in which the general condition became excellent in 2, was much improved in 3, and slightly improved in one; (5) splenic treatment in a case of purulent discharge arising during a course of pneumothorax treatment—the weight went up, the bacilli disappeared, the general state and signs by auscultation improved; and (6) splenic treatment concurrent with pneumothorax and methylic antigen—4 cases, in which the general condition was much improved in 3, and became excellent in the fourth. Tubercle bacilli persisted in 12 cases out of 22, but could not be found in the other 10 even after gastric lavage. Radiograms and charts of temperature and weight are given in some of the cases. The author claims that the treatment is safe and can be used in every case; that great improvement in the general condition ensues, with consequent cicatrization of the lesions and disappearance of physical signs and bacilli; and that it is therefore deserving of a place in the therapeutics of the disease.

19. Treatment of Soft Chancre by Iodoform and Ultra-violet Rays.

V. SOUKHAREFF (*Ann. de Derm. et de Syph.*, October, 1928, p. 869) finds that ultra-violet rays have a bactericidal, antitoxic, and stimulating action on soft chancre. He records eight cases of deeply ulcerated chancres, with inguinal buboes and balanitis, in which this line of treatment resulted in rapid improvement and ultimate cure. Soukhareff believes that iodoform is very useful in these cases; he suggests that the ultra-violet rays decompose it, with the production of nascent iodine and formalin. The technique is very simple. The initial dose is only half of the "erythema dose"—that is, the irradiation lasts for two minutes at a distance of twenty inches. This may be increased gradually to an exposure of ten minutes at a distance of ten inches.

Laryngology and Otology.

20. Nasal Respiratory Inefficiency.

G. WORMS (*Arch. Internat. de Laryngol.*, July–August, 1928, p. 769) describes his course of investigation of patients who show signs of deficient aeration. He investigates the case from two points of view. He measures first the total intake and output of air from the whole respiratory tract, and calculates the relative amounts of respired and residual air. In a vigorous subject with adequate air passages the proportion of residual to respired air is diminished, but in cases of respiratory insufficiency the ratio of residual to respired air is increased, and the tendency is for deficient aeration. The total interchange is estimated by means of some type of spirometer, of which a number are described. At the same time the movements of the chest wall and diaphragm are noted by means of radiography and by an elastic band placed round the chest wall and connected with a tambour. The nasal inefficiency is then calculated by posterior rhinomanometry—by holding a tube, long enough to reach to the fauces, between the closed lips, connecting it with a manometer which is calibrated in millimetres of water, and then breathing through the nose. This method is much more accurate than what is known as rhino-hygrometry—breathing on to a polished surface and estimating the deposition of moisture. When total aeration is normal and nasal respiration is subnormal the diaphragm and costal muscles are compensating by overworking. When the total respiration is decreased but the nasal is normal the nose is not at fault, but the other respiratory apparatus is not functioning normally, and should be re-educated after correcting any organic faults. Where both total and nasal respiration are below normal the fault probably lies in the nose. In children the cause of nasal deficiency is almost always adenoid vegetations; it is advised that these should be removed as soon as diagnosed, the author having operated on an infant of eleven days with consummate success. In adults deflected septa and hypertrophic rhinitis are the commonest defects; these should be removed and breathing exercises undertaken. The narrow nose and the arched palate of the pseudo-adenoid present more difficulty, but much can be done by means of exercises to improve their condition.

21. The Mechanism of Reflex Asthma.

U. L. TORRINI (*Arch. Ital. di Otol.*, September, 1928, p. 510) describes two cases of severe asthma in which cure followed the relief of nasal obstruction. Such obstruction is a very common cause of asthmatic attacks, and there are three ways in which it may set them in motion. The first is that the nerve endings in the nasal mucosa are mechanically compressed, and a reflex action is set up causing spasm of the bronchial muscles. The second is that the obstruction results in an increase in the percentage of carbon dioxide in the upper reaches of the nasal passages which stimulates the nerve endings, and the bulbar centres are irritated. The third theory is that the obstruction produces an excess of carbon dioxide in the blood and that this irritates the bulbar centres and causes the bronchial spasm. The author considers the mechanical theory the true one, since in many cases of complete nasal obstruction there is no asthmatic tendency. The two patients had masses of nasal polypi obstructing the nose and causing very severe asthma. The polypi were removed and a partial ethmoidectomy performed, the nose being packed for forty-eight hours with bismuth gauze; complete relief of symptoms followed. The author considers that the reflex arc consists of the sensory nerve supply of the pituitary epithelium of the nose, a synapse or synapses in the bulb, and an efferent impulse along the vagus to the bronchial muscles.

22. Sensorimotor Neurosis of the Larynx.

H. C. TODD (*Arch. Oto-Laryngol.*, September, 1928, p. 303) reports a case of loss of voice which was eventually found to be due to a laryngeal sensorimotor neurosis. The condition lasted for nearly two years, treatment by rest and sedatives proving useless. At the end of this time laryngeal exercises and the administration of phenobarbital brought about recovery within ten days. Todd discusses these cases, which he thinks are relatively frequent, though often

unrecognized. An important point in the diagnosis is the sudden occurrence of aphonia, without constitutional symptoms or the presence of an extralaryngeal disease which might affect the nerve supply; the larynx itself appears physically normal. The author adds that the condition very rarely persists so long as in the case he reports.

Obstetrics and Gynaecology.

23. Treatment of Septic Abortion.

G. GELLHORN (*Amer. Journ. Obstet. and Gynecol.*, October, 1928, p. 547) estimates that 90 per cent. of all abortions are criminal, and that the percentage of septic abortions is higher than 10. He stresses the advisability of treating any criminal abortion as a septic abortion, and of regarding every septic incomplete abortion as a criminal one until the contrary is proved. Gellhorn, in discussing the general treatment of such conditions, does not recommend the use of serums or vaccines, nor does he favour the intravenous injection of such agents as mercurochrome. He advocates, rather, non-specific protein therapy, where the natural resisting power to infection is raised by intramuscular injections of milk or repeated blood transfusions. With this he combines cardiac stimulation by using intravenous pituitary extract, as recommended by Hofbauer. He has abandoned such measures as the following: (1) the active policy of clearing out the uterus in all cases, and, by so doing, destroying the protective leucocytic barrier and perchance spreading infection; (2) the expectant one of waiting three to eight days and then emptying the uterus when the virulence of the organisms has decreased; (3) the conservative one of administering quinine and pituitary extract only. Instead of these measures he institutes general treatment at once, and does not deal with the uterus if any extrauterine infection is suspected after gentle examination. If gestation products protrude through the os they are removed with placental forceps. If severe haemorrhage is present in the first two days the vagina is packed with iodoform gauze, while on the third day, if no extrauterine complication or tenderness is present, curetting is performed irrespective of fever.

24. Pregnancy and Spontaneous Pneumothorax.

ACCORDING to A. SZENES (*Zentralbl. f. Gynak.*, November 3rd, 1928, p. 2858) spontaneous pneumothorax in pregnancy may occur either in a person suffering from advanced and active pulmonary tuberculosis or in one with apparently healthy lungs. In the former group the prognosis is bad, death being usually not long delayed; in the latter group recovery is the rule, although recurrence may follow (this not necessarily being of grave import). Cases of the second group are indirectly connected with tuberculosis, the cause of the pneumothorax being rupture of an apical emphysematous bulla in the neighbourhood of a scar which is connected with an antecedent healed tuberculous lesion. In these cases the pneumothorax is produced very suddenly, by coughing or singing; unfavourable signs are (1) severe bleeding, especially when this is directed towards the pleural cavity rather than externally, (2) bilateral pneumothorax. The occurrence of pneumothorax is favoured by the deeper thoracic and abdominal breathing from the eighth month of pregnancy onwards. Treatment of the pneumothorax is more urgent than that of the pregnancy, which should be conservative; rest and administration of morphine are called for, and puncture is indicated when the intrapleural pressure is greatly increased. That Caesarean section, for obstetric reasons, is not contraindicated is shown by Real's case, in which this mode of delivery was adopted in a patient with incarcerated pelvic dermoid cyst who had also a therapeutic pneumothorax. In general the occurrence of pneumothorax during pregnancy does not justify the forbidding or interruption of future pregnancy.

25. Melanotic Sarcoma of the Ovary.

J. R. MILLER (*New England Journ. Med.*, October 25th, 1928, p. 830) reports a case of pigmented ovarian neoplasm, with which was associated diffuse discoloration of the skin. The patient at the age of 20 had undergone an operation for the relief of acute obstruction of the ileo-caecal valve. A year later a tumour appeared in the abdomen, and was associated with vomiting and diarrhoea. The skin became increasingly bluish over the entire body, but there were no symptoms referable to the lungs or heart. At an operation a large bluish-black lobulated tumour of the right ovary was removed and diagnosed microscopically as being a melanotic sarcoma. Uninterrupted recovery followed, but four months later the abdominal symptoms returned and several pigmented moles of various sizes became obvious on the abdomen. The patient stated that these moles had always been present, but had not been noticed on previous examinations. She died within two months, and at the necropsy it was found that the suprarenal glands were completely replaced by darkly pigmented tumour growths. The remaining ovary was greatly enlarged and contained deep black tumour masses. The author attributes the skin pigmentation to the presence of a soluble melanin in the blood stream, though the influence of the involvement of the suprarenal glands is not disregarded. They were not invasive, however, and did not look like primary tumours; moreover, they were bilateral.

26. Myomectomy.

CHIFOLLIAU (*La Gynécol.*, August, 1928, p. 475) records four observations of pregnancy following myomectomy. The first patient was treated in 1907 by myomectomy for bleeding which followed childbirth, and was attributed to a single interstitial uterine myoma; subsequently she gave birth to three infants at term, but in 1927 hysterectomy had to be performed, the uterus containing numerous widely distributed myomatous nodules. In the second patient, who went to term, four interstitial and subperitoneal myomata were removed at the age of 33. The third patient aborted at the sixth month, two years after myomectomy, and the fourth patient when last seen was four months pregnant two years after myomectomy, at the age of 37. The author concludes that myomectomy is a relatively simple operation, which, employed in young women with healthy adnexa, gives excellent results; a certain number of recurrences, necessitating second operations, are, however, to be anticipated. Examples of pregnancy continuing to term after conception following myomectomy are also recorded by Labey and by Bazy (ibid., pp. 479 and 480).

27. Muck's Test in Pregnancy, Albuminuria, and Eclampsia.

G. GROSSI (*Ann. di Ostet. e Ginecol.*, October 31st, 1928, p. 1176) records his experience of Muck's test in eclampsia, albuminuria, and pregnancy. The test, described in 1924 (*Münch. med. Woch.*, October 17th), consists in the application of adrenaline chloride (1 in 1,000) to the anterior part of the inferior meatus of the nose; a positive result is shown by the appearance of a silvery grey area of blanching in the mucous membrane which has been touched. This local vaso-constriction is taken as a sign of sympatheticotonia; it is present in bronchial asthma. The test is negative in healthy non-gravid women; during pregnancy, according to the observations of Muck, Seysche, and the present author, it is positive in a considerable majority of women, especially during the second and fifth or sixth month. Grossi has obtained positive results by using the test in eight eclamptics, and a certain proportion of positive reactions in fourteen cases of albuminuria in pregnancy. Similar results have been described by Seysche. These findings are regarded as supporting the view that a reflex arterial spasm and a dysfunction of the vasomotor centre are concerned with the genesis of eclamptic convulsions. In the same connexion attention is directed to the arterial spasms which have been ophthalmoscopically noted in eclamptics.

28. Haemolytic Anaemia in Pregnancy.

W. ALLAN (*Surg., Gynecol. and Obstet.*, November, 1928, p. 659) maintains that the pernicious anaemia of pregnancy, being an acute haemolytic anaemia occurring in women under the age of 35, progressing steadily without remissions, and curable by blood transfusion, should not be classified as an Addisonian pernicious anaemia, which differs from it in being an essentially chronic disease appearing chiefly in men after 35 years of age, being characterized by remissions, and not curable by blood transfusion. The blood picture is similar to that of ordinary pernicious anaemia, with greatly diminished haemoglobin and red cells, a high colour index, and the usual variations in size, shape, and staining reactions of the red cells. Insidious in onset during the later months of pregnancy, the condition is generally discovered after delivery, usually in cases of miscarriage or premature labour. The loss of blood during labour is less than normal, and the child is not affected. In 90 per cent. of the cases directly the uterus is empty blood transfusion stops haemolysis, and there is a prompt recovery. The process is too acute for treatment by liver feeding only, and prompt transfusion is the safest therapeutic measure, though liver feeding may be beneficial after transfusion or during pregnancy as a preventive. The danger of recurrence need not contraindicate subsequent pregnancies under proper supervision, and the promptness with which the condition can be controlled by transfusion renders any suggestion of sterilization to prevent recurrence unwarranted.

Pathology.

29. Action of Ethylene on the Human Body.

J. D. BRUMBAUGH (*Journ. Amer. Med. Assoc.*, August 18th, 1928, p. 462) has made a carefully controlled study of the effects of ethylene-oxygen anaesthesia on the normal human being, without any complicating factors, such as surgical trauma, pre-anaesthetic medication, pathological conditions, and mental anxiety concerning an impending operation. Fifteen men, whose ages ranged from 21 to 37 years, volunteered for this study. A careful physical examination was made in all cases. The anaesthetic was given in the morning while fasting, and without pre-anaesthetic medication. As a preliminary the blood pressure, pulse, and respiration rates were recorded, the urine was examined, and the blood coagulation time, blood sugar, and urea contents, the CO_2 combining power, and the icterus index were determined. The subjects were fully anaesthetized for one hour: 85 per cent. ethylene and 15 per cent. oxygen was given, and this concentration was maintained as fully as the patients' condition would permit. Two standard brands of ethylene gas were employed. During anaesthesia the blood pressure and pulse and respiration rates were recorded every five minutes. At the termination of anaesthesia the various blood tests were repeated. Twenty-four hours after anaesthesia the urine and blood tests were repeated in the fasting state. The recovery time and post-anaesthetic morbidity were recorded. No unpleasant sensations during induction were described; nearly all the subjects lost the power to move before consciousness departed. Four men mentioned a sense of well-being; one talked freely during the second stage. The average time of recovery of consciousness after termination of anaesthesia was one minute forty-four seconds. Only one man had a high icterus index the next day, and he had eaten carrots on the night following anaesthesia. Brumbaugh's observations fail to confirm the statement of two other writers that the icterus index is very high after ethylene-nitrous oxide anaesthesia. He draws the following conclusions. Sensations are pleasant during induction and recovery. Neither the haemoglobin nor the icterus index alters, and there is no appreciable derangement of the biliary system. The blood sugar is definitely increased immediately after anaesthesia, but falls to normal in twenty-four hours. The blood urea is not increased immediately, but the next day there is definite increase. There is a temporary decrease of the CO_2 combining power, but it becomes normal in twenty-four hours. There are no changes in the coagulation time of the blood, the character of the blood clot, or the urine. Systolic and diastolic blood pressures are definitely increased during anaesthesia, but the pulse rate is not affected. Headache, nausea, and vomiting are much more frequent than in ordinary surgical anaesthesia; this is attributed to the absence of pre-anaesthetic medication and of careful post-anaesthetic control. Brumbaugh adds that he cannot draw comparisons with other anaesthetics, since he knows of no similar observations by others.

30. The Behaviour of Variola Vaccine Virus in Tissue Cultures.

E. HAAGEN (*Centralbl. f. Bakt.*, October 26th, 1928, p. 31) describes a method for the *in vitro* cultivation of vaccinia virus. The medium he uses consists of four parts of rabbit plasma and one part of rabbit spleen extract. Small drops of this mixture are placed on mica slips, and in each drop is deposited a tiny piece of rabbit testicle. The slips are then placed over hollow-ground slides, ringed round with paraffin, and incubated in the ordinary way. After three days pieces of testicle are taken out from the cultures and immersed for two or three minutes in a vaccine-containing fluid. This fluid is prepared by centrifuging the ground-up testicle of a rabbit that has received, four or five days previously, an intratesticular inoculation of vaccinia virus, and pipetting off the supernatant fluid. Each of the testicular explants, after being infected with the virus, is introduced into a fresh drop of culture medium and again incubated. Subcultures are made every four or five days. In order to guard against the dying out of the testicular culture, and hence of the virus, it is advisable at each subculture to add a small piece of fresh testicle. Using this method the author has been able to cultivate the vaccinia virus successfully; the virus was carried through 37 passages during a period of about eight months. From time to time the virulence of the virus was tested by removing a number of explants, grinding them up in an agate mortar, suspending them in 2 c.cm. of Ringer's solution, making suitable dilutions, and inoculating these into the cornea or the testicle of healthy rabbits. The results showed that the virulence of the virus remained about the same during the whole period of cultivation. Quantitative titrations rendered it clear that the virus not only remained alive but actually multiplied in the tissue cultures; in five days after inoculating the infected testicle into the medium the infective titre rose from 1 in 10,000 to about 1 in 10,000,000.

31. Ultramicroscopical Appearances in the Wassermann Test.

E. TRENTI (*Il Policlinico*, Sez. Med., October 1st, 1928, p. 525) found that by filtering a mixture of a syphilitic serum with a watery or alcoholic antigen through a colloidal membrane a precipitate immediately appeared. After filtering off the precipitate no traces of the antigen or the serum could be demonstrated in the filtrate, unless excess of either were present in the original mixture. By using the precipitate suspended in physiological solution complete deviation of the complement was obtained. The considerable physical modification caused by filtration did not alter the result of a subsequent Wassermann test performed with the filtrate. Both macroscopical and ultramicroscopical observations showed that a non-syphilitic serum gave a negative Wassermann reaction, but in certain cases, such as hepatic cirrhosis, a serum, although not syphilitic, could give a positive reaction. This method of filtration was claimed to give a means of distinguishing between a non-specific, self-deviated serum and a syphilitic one. The author is inclined to think that the inactivation of the complement in the Wassermann test is of the same order of phenomenon as that which caused the formation of a precipitate by the serum and antigen. The precipitate was insoluble in physiological saline solution and in distilled water. Its formation seemed to be in the nature of a chemical or bio-chemical bond, rather than a simple flocculation due to physical or physico-chemical processes. The ultramicroscopic observations confirmed the results obtained by filtration, and also those previously noted by Jacobsthal. But with his method the formation of a flocculent precipitate occurred only after several hours in the incubator, while with the filtration method the presence of a precipitate was immediately demonstrable almost before filtration was complete.

32. The Basis of Suprarenal Cortex Therapy.

J. MOUZON (*Presse Méd.*, October 31st, 1928, p. 1379) calls attention to the fact that experimental research on the suprarenal gland has been largely devoted to the medullary portion, to the neglect of the cortex, although, in animals deprived of the whole gland, it is the absence of the cortical portion which causes death. In the course of a comprehensive though rapid review of the experimental work on this subject he mentions that cases of Addison's disease have been temporarily improved by the administration of cortical extract by injection and by ingestion. He also cites a case of Goldzieher and Greenwald where a newly born infant, exhibiting signs of acute suprarenal insufficiency, probably caused by a suprarenal haemorrhage, was treated by intravenous and subcutaneous injections of "cortical hormone" for a fortnight. After each injection the signs improved and ultimately the child was cured. Many workers claim to have produced an extract from the cortical portion which appears to have a potent therapeutic value, sometimes being antagonistic to adrenaline. The author prefers for the present to keep an open mind, and concludes by suggesting that in practice we should confine ourselves to the view that treatment by suprarenal extracts, often recommended in acute or chronic suprarenal insufficiency, appears more and more firmly based on physiology, and that certain facts even induce the hope that this branch of therapeutics may become in the future more reliable and constant, either by the successful isolation of a definite specific chemical hormone, or at least by its ability to be controlled as to potency and dosage by biological tests.

33. Bactericidal Action of Cerebro-spinal Fluid.

T. SHIMIDZU (*Tohoku Journ. of Exper. Med.*, October 28th, 1928, p. 344) finds that the bactericidal power of cerebro-spinal fluid which has been heated to 100° C. for thirty minutes depends on the altered *p*H of the fluid causing an unsuitable alkalinity for the growth of the bacteria (*B. typhosus*) used in the experiments. When a requisite amount of potassium hydrogen phosphate is added to regain the optimal *p*H an uninterrupted growth of the organisms occurs in both the active and inactivated fluids. The bactericidal action of inactivated lymph seems to have no relation to the hydrogen-ion concentration. Most human serums retain the bactericidal property after heating to 60° C. for thirty minutes, and no relation to the hydrogen-ion concentration is observed. With active human serum in which the *p*H has been chemically adjusted there is no diminution of the bactericidal power. If the *p*H is similarly adjusted in serums previously inactivated by heat the bactericidal action is sometimes lost and sometimes retained, and shows no consistent relation to the hydrogen-ion concentration.

CAREL A. HOEFFTCKE

7, HARLEY STREET, LONDON, W.1.

Inventor and Maker of Hoefftcke's Extension Appliance.

The benefits of my Ambulatory Extension Treatment have been described by many eminent medical men in cases of tubercular diseases of hip, knee, and ankle joints, fractures of the long bones, especially neck of femur fractures, and cases of Osteo-Arthritis of the hip and those of Rheumatoid origin of knee and ankle.

The main advantage of the use of the extension appliance for those cases is that the patient is enabled to walk about and lead an active life while extension is maintained between the fragments of the fractures and between the articulating surfaces in diseased joints. By means of active movement the circulation of the parts is not restricted as in the recumbent treatment.

Union of fractures, even in the so-called un-united fractures, has been greatly assisted by active movement, and subsequent improved circulation of the blood.

In those of the arthritic conditions, cases have been described where inflammatory changes in the articulating surfaces have been restored to the normal with complete active movement as a result.

Some of the hospital cases of tubercular joint diseases were treated while the patients lived in the poor districts of London, and still good results were obtained.

In many of the Rheumatoidal cases, especially where knees were contracted, the first part of the treatment had to be carried out in the home of the patient, owing to the impossibility of the patient being moved, due to the pain in the joints.

A great improvement in most of the cases was obtained if the patients were able to convalesce in certain parts of the country. My experience has taught me that sea air, especially on the East Coast, is detrimental to the extension treatment of Rheumatoid Arthritic cases, hilly and mountainous districts always exerting a more beneficial action on the diseased joint.

For about twenty years I have suggested to the surgeons and physicians who have sent me their cases that they should advise their patients in the convalescent stage to spend a certain time in a place called Trefriw, in North Wales. The valley of the Conway enjoys a climate very much the same as that of the south of France, and statistics show that in Trefriw the temperature in winter is much higher and the yearly rainfall much less than in London.

In addition to the beautiful mountain air, the patients are able to derive great benefit from the strong Ferrous Sulphate waters obtainable at Trefriw.

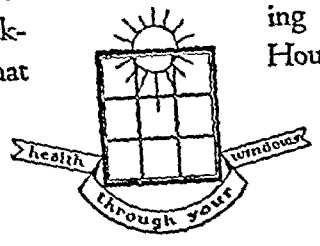
In order that I may carry out my treatment under the supervision of medical men who send me their cases, and, if necessary, of a visiting physician, a number of my friends and I have formed a private limited company—AMBULATORY TREATMENT, LTD.—which has taken over the Bellvue Hotel at Trefriw. This hotel is now being altered and reconstructed to fulfil the requirements necessary for the ambulatory treatment.

Any inquiries should be addressed to 7, Harley Street, London, W.1.

Natural Sunlight as an aid to Individual Treatment

MANY medical men are finding that natural sunlight through "Vita" Glass acts as a valuable adjuvant when used in conjunction with their own individual treatment of patients. "Vita" Glass, which is a product of British science and British industry, is accepted by eminent authorities as a means of transmitting the biological and therapeutic wave-lengths of the ultra-violet rays, which ordinary window glass shuts out entirely. "Vita" Glass introduces a gentle, sheltered heliotherapy into the sick-room, and now that substantial reductions have been made in prices medical men may safely prescribe "Vita" Glass windows for patients of only moderate means.

Authentic information is available of the beneficial effects of sunlight obtained through "Vita" Glass under strict test conditions in Hospitals, Sanatoria, Schools, Offices, Factories and private houses. Medical men interested in "Vita" Glass for their own homes or for their patients are invited to write for full particulars to "Vita" Glass Marketing Board, 9 Aldwych House, London, W.C.2.



"VITA" GLASS

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers or Builders.
"Vita" is the registered Trade Mark of Pilkington Brothers, Limited, St. Helens.

767

The awkwardness of having to depend upon a phrase book on your visits abroad disappears when you have learnt to speak Foreign Languages by the new Pelman method. A book describing this method will be sent, gratis and post free, to every reader using the coupon printed below.

HOW TO BECOME AN EXPERT LINGUIST.

Wonderful Success of New Pelman Method of Learning Foreign Languages.

COULD you pick up a book, written in some Foreign Language of which you do not know a syllable, and read it through correctly without once referring to a dictionary?

Most people will reply "No. It would be impossible!"

Yet this is just what the new method of learning French, Spanish, Italian, and German, taught by the famous Pelman Institute, now enables you to do.

A Personal Experience.

The present writer can speak with knowledge on this subject.

Calling at the Institute to inquire into this new method he was asked whether he knew any Spanish. He replied that with the exception of a few words like "*primavera*," which he knew meant "Spring," he was entirely unacquainted with the language.

He was then handed a little book of 48 pages, printed entirely in Spanish, and asked to read it through.

There was not a single English word in this book, yet, to his utter amazement, he was able to read it from cover to cover without a mistake.

This is typical of the experiences of thousands of people who are learning French, Spanish, Italian, or German by this new method. Here are a few examples of letters received from those who are following it:—

"I have learnt more French during the last three months from your Course than I learnt during some four or five years' teaching on old-fashioned lines at school." (S. 382.)

"I have spent some 100 hours on German studying by your methods; the results obtained in so short a time are amazing." (G.P. 136.)

"I can read and speak Spanish with ease, though it is less than six months since I began." (S.M. 181.)

"I have obtained a remunerative post in the City solely on the merits of my Italian. I was absolutely ignorant of the language before I began your Course eight months ago." (I.F. 121.)

Matriculation Passed.

"I was able to pass London matriculation (in Spanish) last June with minimum labour and no drudgery, although I was always reckoned a 'dud' at languages." (S.B 373.)

"My grateful thanks to you for making so attractive the learning of French. I am 40 next week and am delighted to be able to say I accomplished at 40 what I turned aside from at 20 as too difficult." (T. 656.)

"I have only been learning German for four months; now I can not only read it but also speak it well." (G.M. 148.)

"I am extremely pleased with the (Italian) Course. I found it of the greatest possible service to me during a recent visit to Italy." (I.T. 127.)

"Your method is the pleasantest method of learning a language imaginable. I always found languages a very difficult subject at school, but have had no difficulty whatever with the (French) Course." (P. 684.)

"This is the perfectly delightful method (of learning Italian), and I shall not fail to recommend it to everyone I meet." (I.L. 108.)

"I am entirely satisfied with this (French) Course, and am especially pleased at the way in which all faults have been corrected and explained by your staff." (B. 1329.)

"How pleased I was when I heard that I had been successful in my examination. I attribute my success almost wholly to your methods, which are undoubtedly very good" (C. 885.)

"Having completed Part I of your French Course, and thereby improving my knowledge of the language almost beyond belief, I should now like to take Parts II and III." (S. 751.)

"I think your (French) Course is the best method I have ever seen." (C. 272.)

"Regarding the (Spanish) Course, I must say that I find the method perfection, and the learning of a language in this way is a pleasure. It is simple and thorough." (S.F. 109.)

"I think your German Course excellent—your method of language-teaching is quite the best I have come across." (G.F. 103.)

"In three months I have already learnt more Italian than I should have learnt in many years of study in the usual way. What astonishes me still more is that one can learn so well without using a single word of English." (I.M. 124.)

No Translation.

This new method enables you to learn French in French, Spanish in Spanish, German in German, and Italian in Italian.

It enables you to learn a language as a Spaniard, Italian, Frenchman, or German learns it. There is no translation from one language into another.

It enables you to think in the particular language in question.

It thus enables you to speak without that hesitation which arises from the habit of mentally translating English phrases into their foreign equivalents.

There are no vocabularies to be memorised. You learn the words you need by using them and so that they stay in your mind without effort.

No Grammatical Difficulties.

Grammatical complexities are eliminated. You pick up the grammar almost unconsciously as you go along.

This makes the new method extremely interesting. The usual boredom of learning a Foreign Language is entirely eliminated.

There are no classes to attend. The whole of the instruction is given through the post.

WRITE FOR FREE BOOK TO-DAY.

The new Pelman method of learning French, German, Italian, and Spanish is explained in four little books.

One describes the Pelman French Course.
Another describes the Pelman Spanish Course.
A third describes the Pelman German Course.
A fourth describes the Pelman Italian Course.

You can have a free copy of any one of these books by writing for it to-day to the Pelman Institute (Languages Dept.), 74, Pelman House, Bloomsbury Street, London, W.C.1.

State which book you want, and a copy will be sent you by return, gratis and post free. Write or call to-day.

FREE APPLICATION FORM.

To the PELMAN INSTITUTE (Languages Dept.), 74, Pelman House, Bloomsbury St., LONDON, W.C.1.

Please send me, post paid, a free copy of "THE GIFT OF TONGUES," with full particulars of the new Pelman Method of learning

"FRENCH" | "SPANISH" } *Cross out three of these*
"GERMAN" | "ITALIAN" } *without using English.*

Nota Bene—IS YOUR ADDRESS BOOK COMPLETE?

Any well-kept Professional Address Book reveals

John Bell & Croyden, 50, Wigmore St., W.1, for all Professional Requirements.

Many contain cross reference

See Arnold & Sons, also at 8, Welbeck St., W.1, for Special Surgical Appliances.

SURGICAL APPLIANCES DEPARTMENT

Is expressly equipped for the supply of not only stock patterns, but with facilities for making any variations necessary to meet peculiar cases. Abdominal Belts, Trusses, Elastic Hosiery, Artificial Limbs, Splints, Orthopaedic Fittings, etc., etc., are available. An experienced staff of Male and Female Fitters; consulting, fitting, and waiting rooms well heated and lighted; provide for convenience and immediate comfort of patients.

SURGICAL APPLIANCES

Should fit correctly and be comfortable. Practical mechanical skilled fitters ensure to the Profession a service of great value. The staff maintained is practically identical with that employed by **Messrs. ARNOLD & SONS** for many years in Giltspur Street, E.C., well remembered by those of the Profession who were trained in the City of London.

Prescriptions and post orders receive the greatest attention. Where patients are unable to attend arrangements can be made for fitters to visit all parts.

To Relieve Chronic Intestinal Stasis in Women

When you have a patient with chronic intestinal stasis due to diminished tonicity and stretching of abdominal muscles following a pregnancy, you will obtain excellent results from the mechanical support provided by a Spencer Belt.

Equally satisfactory results are obtained by the use of a Spencer Abdominal Belt for cases where atrophy and diminished tonicity are due to toxemia and loss of fat following a severe illness or an abdominal operation, or in any case where enteroptosis exists.

SPENCER BELT

The back of the Spencer Belt is made long enough for comfort, and to provide adequate back support.

The front of the garment curves in snugly to the pubic bone, and is so designed and adjusted that it uplifts the abdomen instead of compressing it.

Spencer Belts to relieve chronic intestinal stasis will be provided with ptosis pads if the physician desires it.

Each Spencer Belt is designed to meet the special needs of the individual who will wear it. You can therefore prescribe and obtain exactly what your patient needs.

The Spencer Corsetière will call at your surgery or at your patient's home to take measurements under your supervision.

We issue booklets on the use of Spencer Supports for the relief of enteroptosis, hernia, movable kidney, sacro-iliac strain, and for maternity wear. We will gladly send you any in which you are interested.

Prescribe HORLICK'S

Even the weakest patients, with virtually no energy to digest food of any kind, can frequently assimilate and retain Horlick's when all other foods are rejected.

4 big advantages

DONIGER Krome-Plate Surgical Instruments possess four big advantages over ordinary nickel-plated instruments. They are:

(a) much harder and stronger;
(b) rust-resisting;
(c) last five times as long as nickel;
(d) retain their original brightness.

These are facts that have been proved under practical conditions in many important hospitals and clinics in America where Doniger Instruments are used consistently.

Doniger Instruments are made from high carbon steel specially polished to ensure perfect smoothness, then nickel-plated, and finally given a generous coating of chromium. Despite the high quality of the materials and craftsmanship employed, Doniger Instruments cost only a fraction more than nickel-plated instruments.

You are invited to apply to your usual Supply House for full particulars and prices.

Doniger Instruments are not supplied direct to the Profession.

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It leaves hands free.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE. *Mr. R. H. Dent makes a Stethoscope especially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the worst, which delighted Medical Men at the recent B.M.A. Meeting.*

MEDICAL REPORTS. *Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.*

WHOOPING COUGH

Vapo-Cresolene Est. 1879

Sold by Chemists

Write for descriptive Booklet No. 67A.

The best practice in the treatment of whooping cough recognizes the importance of keeping the patient out of doors as much as possible. The food should be easily digestible, nourishing, and given a little at frequent intervals.
There are no specifics for this disease. In very young children drugs are administered with difficulty and are of uncertain effect.
Vaporized Cresolene at night will be found a simple and effective means of preventing the paroxysms at that time, thus tending to preserve the strength of the patient, avoid complications, and hasten convalescence.

Royal Northern Hospital,
Holloway, London, N.

A vacancy occurs for an OBSTETRIC PHYSICIAN to the Hospital, and applications are invited for the appointment.

Candidates must possess the Degree of M.D. or M.B. obtained by examination at a British University and be Fellows of the Royal College of Surgeons of England.

Particulars of the office and details with regard to the submission of testimonials, etc., may be obtained from the undersigned, to whom applications should be sent not later than January 15th.

GILBERT G. PANTER, Secretary.

WEST AFRICAN MEDICAL STAFF

VACANCIES exist for MEDICAL OFFICERS and MEDICAL OFFICERS OF HEALTH in the BRITISH WEST AFRICAN COLONIES.

SALARIES.

Medical Officers receive salaries at the rate of £660 a year, rising by annual increments of £30 to £720 a year, and then on confirmation £720 a year, rising by annual increments of £40 to £960 a year, together with a seniority allowance (payable only in West Africa) at the rate of £72 a year. After three years' service on £960, the salary may be raised to the scale of £1,000 a year, rising by annual increments of £50 to £1,150 a year, together with a seniority allowance at the rate of £100 a year.

Medical Officers of Health receive salary on the above scale beginning at £800 a year, together with seniority allowance of £72 a year. They also draw staff pay at the rate of £150 a year, half of which is payable during leave.

QUARTERS.

Free furnished quarters are provided or an allowance in lieu.

OUTFIT ALLOWANCE.

An outfit allowance of £60 is granted on first appointment.

PASSAGES.

Free first-class passages are provided on first appointment, and when proceeding on or returning from leave.

PENSIONS.

All appointments are pensionable; a minimum service of seven years is required to qualify for a pension. An officer may retire on reaching the age of 50 and may be called upon to retire at the age of 55. Officers of the West African Medical Staff are permitted to retire if they wish with a gratuity of £1,000 or £1,250 after nine or twelve years' approved service respectively, but in that event they receive no pension.

TOURS OF SERVICE AND LEAVE.

A tour of service in West Africa lasts from twelve to eighteen months at the discretion of the Colonial Government, and is followed by leave at the rate of one week for each completed month of residential service. Leave begins on the date of arrival in England.

PROMOTION.

There are good prospects of promotion in the West African Medical Staff.

COURSE OF INSTRUCTION.

Selected candidates are required to attend courses of instruction in tropical medicine and hygiene at either the London School of Hygiene and Tropical Medicine or the Liverpool School of Tropical Medicine or the University of Edinburgh.

Further information regarding the conditions of service, pensions, etc., may be obtained from the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, Whitehall, London, S.W.1, to whom applications should also be addressed.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian service for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Year of Total Service.
1	2	3	4	5
		Rs.	Rs.	
Lieut.		500	150	1st
			150	2nd
			150	3rd
Capt.	(i) During first 3 years' service as Captain	650	150	4th
			£15	5th
			£15	6th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	7th
			£25	8th
			£25	9th
	(iii) With more than 6 years' service as Captain	850	£25	10th
			£25	11th
			£30	12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut.-Col.	(i) Until completion of 23 years' total service	1500	£30	13th and over
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

WAR SERVICE CONCESSIONS.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:

	Per annum. £
After 17 years' service for pension	400
,, 18 ,, ,, ,, ...	430
,, 19 ,, ,, ,, ...	460
,, 20 ,, ,, ,, ...	500
,, 21 ,, ,, ,, ...	540
,, 22 ,, ,, ,, ...	580
,, 23 ,, ,, ,, ...	620
,, 24 ,, ,, ,, ...	660
,, 25 ,, ,, ,, ...	700
,, 26 ,, ,, ,, ...	750
,, 27 ,, ,, ,, ...	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. Applications should be submitted as soon as possible. The Selection Committee will meet shortly to make nominations, and the selected candidates will be required to attend a course of instruction commencing on February 4th, 1929.

The Barbados General Hospital.

Wanted, a duly qualified medical practitioner (male) as JUNIOR RESIDENT SURGEON of The Barbados General Hospital (224 beds). A man who has had experience in administering anæsthetics preferred.

Salary £250 per annum, with a temporary addition of 20 per cent., and quarters furnished for a single man, free water, lighting allowance, and no local rates. The appointment is for three years, with three months' notice on either side to terminate the engagement, and first-class passage out (direct from England) will be paid by the Hospital for the full term of service.

Applications, accompanied by a recent medical certificate of physical fitness, and professional and other testimonials, stating age and date of graduation, will be received by Dr. A. A. GIBBONS, at "Balmoral," 34, Prince's Square, Bayswater, London, W.2, and should reach him not later than January 15th, 1929.

Canadian Graduates must be registered in a province, registration in which will entitle them to be registered in the United Kingdom.

Candidates holding a United States degree must be registered in the State of New York.

By Order of the Court of Trustees and Directors,

General Hospital, Bridgetown, Barbados, B.W.I. J. WARD, Secretary.

Applications are invited for the post of a DENTAL SURGEON and a DENTAL MECHANIC for the DENTAL HOSPITAL to be established in LAHORE, on a pay of Rs.1,000—50—1,500 and Rs.400—20—800 per mensem respectively.

Candidates for the post of Dental Surgeon should possess a British or American registrable qualification in Dentistry, and should have undergone a special course of instruction in the theory and practice of Dental Surgery, and must produce documentary evidence to show that they are capable of imparting instruction in the subject.

Candidates should state their age, qualifications, experience, present appointment, place of domicile and nationality, and should submit their applications, with attested copies of certificates and testimonials (which will not be returned), not later than February 15th, addressed to the Inspector General of Civil Hospitals, Punjab, Lahore.

The Sudan Government.

A MEDICAL OFFICER is required for Public Health duty for the Sudan Medical Service.

The candidate should be single, under 30 years of age, and he must have a D.P.H. Degree.

Pay for the post commences at £E.780, rising by degrees to £E.1,200. On confirmation of the appointment the selected candidate will be eligible for Pension Service.

Applications (in writing only), with copies of recent testimonials, should be sent to Dr. HODSON, 100, Harley Street, W.1, from whom further particulars can be obtained.

Warrington Infirmary and DISPENSARY.

HONORARY MEDICAL STAFF.

The Board of Management invite applications for the positions of TWO ASSISTANT HONORARY SURGEONS to the above Institution. Candidates must be legally registered to practise medicine and surgery, and shall be resident in the area served by the Institution.

Applications, stating age and qualifications, should be sent in to the Chairman of the Board of Management not later than Thursday, January 24th.

By Order of the Board,
HENRY L. BOOT,
December 24th, 1928. Supt. & Secretary.

Victoria Hospital, Blackpool. (132 Beds.)

HOUSE SURGEON (Second), male. Salary £120 per annum, with residence, board, and washing. Applicants (who must be duly qualified and registered) are requested to send in their applications, stating age, qualifications, and experience, with three recent testimonials, not later than January 8th, and endorsed "House Surgeon," to—

JOHN HACKING, Hon. Secretary.

Rochdale Infirmary and DISPENSARY. (110 Beds.)

Wanted, JUNIOR HOUSE SURGEON (male). Salary £175 p.a., including board, residence, and laundry. Applications, stating age, nationality, etc., together with copies of three testimonials, to be sent to the Secretary, endorsed "House Surgeon." Conditions of appointment may be had on application to the Secretary.

Infirmary Office, Rochdale. W. WYNNE, Secretary.

West Derby Union.

RESIDENT ASSISTANT MEDICAL OFFICER (Male).

The Guardians invite applications for the above position at the MILL ROAD INFIRMARY, EVERTON, LIVERPOOL, and also at the SMITHDOWN ROAD INSTITUTION, LIVERPOOL, at a salary after the rate of £200 per annum, together with rations, apartments, etc.

Candidates must be single, fully qualified, and registered.

Appointment will be for a period of one year in the first instance, subject to one month's notice to terminate on either side at any time, and to extension for a further period of twelve months at the option of the Guardians.

Applications to be sent, stating age, qualifications, etc., with copies of three recent testimonials, to the undersigned not later than first post on Monday, January 14th.

Union Offices, Brougham Terrace, Liverpool. G. O. HOLLOWAY, Clerk to the Guardians.

December 28th, 1928.

Swansea County Borough.

ASSISTANT MEDICAL OFFICER.

The Swansea Borough Council invite the applications from duly qualified medical practitioners for the post of Assistant Medical Officer to assist with the Medical services of the Corporation.

Resident hospital, school medical service, maternity and child welfare experience, together with special experience in the treatment of venereal diseases of women and children, are desirable qualifications.

Salary £600 per annum, subject to B.M.A. scale conditions. The appointment is subject to the approval of the Ministry of Health and Board of Education.

Applications, on special forms, which can be obtained from Dr. THOMAS EVANS, Medical Officer of Health, Public Health Office, Swansea, to be sent in not later than January 11th, 1929.

County of London.

The London County Council invite applications for appointment as EIGHTH ASSISTANT MEDICAL OFFICER (male) in its MENTAL HOSPITAL SERVICE. Candidates must be under 35 years of age and be registered to practise both in medicine and surgery in England. Salary £300 a year, rising by annual increments of £25 to £400 a year, plus fluctuating temporary additions, the present total commencing remuneration being approximately £414 a year. No emoluments. Charges made for board, lodging, etc. (at present £2 9s. weekly) if required to be resident. Candidates appointed will be pensionable under the Asylums Officers Superannuation Act, 1909. Form of application, on which full particulars are given, can be obtained from the Acting Chief Officer, Mental Hospitals Department, The County Hall, Westminster Bridge, S.E.1. Completed applications must be received by Tuesday, January 15th.

Canvassing disqualifies.

MONTAGU H. COX,
CLERK of the London County Council.

Willesden General Hospital.

SURGICAL OUT-PATIENT DEPARTMENT.

Applications are invited for the appointment of CLINICAL ASSISTANTS to the Surgical Out-patient Department, which is held on Monday and Friday at 2 p.m.

The successful applicants will be expected to attend the Hospital regularly, and to take charge of the Department when the Medical Officer is absent. The appointment is for a period of six months from January 1st.

Applications should be addressed to the undersigned not later than Wednesday, January 16th, from whom full particulars of the appointment can be obtained.

R. J. HEARNE,
November 26th, 1928. Secretary.

The King Edward VII Welsh NATIONAL MEMORIAL ASSOCIATION.

Required immediately at the NORTH WALES SANATORIUM, LLANGWYFAN, near DENBIGH (236 beds for Pulmonary and non-Pulmonary cases), THIRD ASSISTANT RESIDENT MEDICAL OFFICER (male). Salary £250 per annum, plus maintenance. This appointment is limited to a period of one year.

Applications, stating age, qualifications, and previous experience, together with copies of three recent testimonials, should reach the undersigned not later than Thursday, January 10th.

Memorial Offices, Westgate Street, Cardiff. D. A. POWELL, Prinicipal Medical Officer.

West Ham Union.

SPECIALIST CONSULTANTS.

The Guardians invite applications for posts as Specialist Consultants at their WHIPPS CROSS HOSPITAL, Whipps Cross Road, Leytonstone, E.11, as detailed below.

Applicants must be definitely of consultant rank and must be attached in that capacity to some Special Hospital or to a corresponding Special Department of a General Hospital.

The duties will consist of making visits to the Hospital, there to treat (or advise as to treatment in) such cases as are selected by the Medical Superintendent. The duration of each visit would vary with the number of cases arising; emergency visits, if any, would be very rare.

GYNÆCOLOGIST. Attendance when requested. Retaining fee of £50 p.a. and £5 5s. per visit.

ORTHOPÆDIC SURGEON. One afternoon fortnightly. Salary £100 p.a.

OPHTHALMIC SURGEON. One afternoon fortnightly. Salary £100 p.a.

NEUROLOGIST. One afternoon fortnightly. Salary £100 p.a.

The services of the Consultants will be retained for a period of one year in the first instance, and each Consultant will be required to provide his own locum tenens during holidays and absences.

Further information can be obtained from the Medical Superintendent at the Hospital by letter, or preferably by interview.

Applications, with copy testimonials, should reach the undersigned not later than 10 a.m. on Monday, January 28th.

Board Room, Union Road, Leytonstone, E.11. L. E. FRAQUET, Clerk to the Guardians.

January 1st, 1929.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place, Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. *Telephone*: GERRARD 3643 (3 Lines).

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. LONDON, NORTH-WEST.—GOOD RESIDENTIAL SUBURB.—Very sound well-established non-dispensing, non-panel PRACTICE, held many years by present incumbent, who is retiring owing to advancing age. Average cash receipts for the past three years £2,222. Exceptionally good residence, with ample accommodation. Price for freehold £3,750. Premium 1½ years' purchase.

2. KENT.—GROWING DISTRICT, within 15 miles of London.—PARTNERSHIP.—A one-half share is for disposal in a very sound chiefly better and middle-class Practice, established many years, and held by the remaining partner over 4 years. Gross cash receipts for the past three years £2,528, including panel of 900. No appointments. Fees from 5/- to 21/-. Midwifery 3 to 30 guineas (about 25 cases yearly). Very suitable modern house, with 2 reception, 4 bedrooms, good bathroom, etc. Consulting room. Electric light. Small garden. Garage. Price for freehold about £2,100, nearly all of which could remain on mortgage. Good sport and schools, and excellent social facilities. Premium 2 years' purchase.

3. NOTTINGHAM.—Good middle-class PRACTICE offering good scope and having small panel which could be largely increased. Gross cash receipts are between £600 and £700 p.a. Fees 5/6 to 21/-, medicine extra. Very good modern corner house in pleasant residential district. Rent on lease £80 p.a. Premium £900.

4. ESSEX.—SMALL COUNTRY TOWN.—Well-established and increasing PRACTICE, producing for the past twelve months £768, including panel of 525, and appointments worth over £60 p.a. Advice and medicine chiefly 3/6 to 7/6, visits 3/6 to 21/-, medicine extra. Mids. (discouraged) 2 to 5 guineas. [illegible] nice house, with rooms lounge hall, 3 reception, 5 bedrooms, garden, and usual offices. Hot water supply, [illegible] Price with tennis court. Garage for two cars. for freehold £3,100. Premium 1½ years' purchase.

5. LANCASHIRE.—SUBURB OF LARGE TOWN.—Old-established PRACTICE, held by Vendor 30 years. Average income for the past twelve months £1,530, including panel of nearly 1,500. Fees 2/6 to 10/-. Very good house, standing in its own grounds, and containing 3 reception, 4 bedrooms, dressing room, 3 professional rooms. Central heating. Electric light. Garden, with greenhouse. Garage for 3 cars. Price for leasehold £2,100, of which about £1,500 could remain on mortgage. Premium 1½ years' purchase, part by instalments.

6. LONDON, NORTH.—OUTLYING RESIDENTIAL SUBURB.—PARTNERSHIP.—A one-third share (to commence with) is for disposal, owing to the retirement of the senior partner, in sound middle-class Practice, situated in rapidly developing district. Income for the immediate past year £2,124. Consultations 3/6 to 10/6, visits 4/6 to 21/-. Good freehold house, price £1,500; or would be rented on lease at £90 p.a. Low expenses. Premium 2 years' purchase.

7. OUTLYING WESTERN SUBURB.—Old-established mixed general PRACTICE. Income for the immediate past year about £2,300, including panel of between 1,400 and 1,500. Fees 3/6 to 10/6. Midwifery from 3 gns. The district is rapidly developing and there is great scope. Good house, with garden and garage. Price £2,000. Premium £5,500.

8. NEAR CROYDON.—Very well-established growing mixed general PRACTICE, situated in pleasant district within easy reach of town. Gross cash receipts for immediate past twelve months nearly £2,650. Panel of 2,120. Appointments worth about £60 and stated to be transferable. Fees 2/6 to 7/6. Midwifery from 3 gns. (about 40 cases yearly. Moderate expenses. Seven-roomed house, with kitchen, 2 waiting rooms, dispensary, and consulting room. Garden. Brick-built garage. Price for freehold £1,500. Premium £4,500.

9. NORTH DEVON.—COUNTRY TOWN.—A one-third share (with increase up to one-half later) in a very old-established and increasing mixed-class PRACTICE, averaging about £3,000 p.a., including panel of over 2,100, and appts. worth nearly £150. Fees 3/6 to [illegible] 2 to 7 gns. Choice of houses. Sport of all kinds [illegible] 2 years' purchase, part by arrangement if [illegible] outdoor assistantship offered at a salary of £450 p.a. Scotch Graduate preferred, about 30 years of age.

10. SOUTH OF ENGLAND.—FAVOURITE SEASIDE RESORT.—Mainly better-class PRACTICE, producing for the last twelve months about £700, and rapidly increasing. Panel of 150. One appt. worth about £40 p.a. Fees 3/6 to 7/6. Only a few cases of midwifery. 2 gns upwards. Good house in excellent repair, with 2 reception, 5 bedrooms, etc. Electric light. Garden. Garage. Price for freehold £2,300. Premium £1,400.

11. MIDLANDS.—COUNTRY PRACTICE, within 100 miles of London. Easily worked practice, producing about £1,000 to £1,200 p.a., including panel of 600. Large and exceptionally attractive house, in first-rate order, with 3 reception, 11 bedrooms, and professional accommodation, etc. Electric light. Stabling for four horses. Well-stocked garden of 1½ acres, and several acres of grassland. Good hunting centre. Price for practice and house £6,500.

12. PARTNERSHIP.—PLEASANT SURREY SUBURB.—The Third Share of an old-established Practice offers to a purchaser desirous of doing major and minor surgery owing to the retirement of the junior partner through prolonged ill health. Held by senior 24 years. Cash receipts about £2,700 p.a., including appts. worth about £340, and panel 1,000. Visits 3/6 to 21/-. Mids. 3 gns. upwards, 75 cases yearly. House available containing consulting room, dispensary, 2 reception, 6 bedrooms, bathroom. Garage. Rent £85 p.a. Premium 2 years' purchase. Hospital (27 beds) in the place, and excellent scope.

13. CHANNEL ISLANDS.—Old-established general PRACTICE. Present income approximately £700, but large scope. Advice and medicine 3/6 to 10/6, visits and medicine 5/- to 15/-. Midwifery refused. Commodious house, with 2 reception, 6 bedrooms, etc. Vendor's freehold. Good schools. Price for practice and house £3,000.

14. WEST OF ENGLAND.—Very easily worked unopposed Country PRACTICE, averaging about £600 p.a., including panel of 500. Fees from 2/6 to 12/6. Midwifery 3 to 5 gns. Nice house, with 2 reception, 6 bedrooms, etc., professional rooms. Large garden and paddock. Price for freehold £1,200. Premium 1½ years' purchase.

15. BORDERS OF NORFOLK AND SUFFOLK.—Old-established middle-class PRACTICE, producing about £1,100 p.a., including panel of over 500. Visits 3/6 upwards. Midwifery from 2 gns., about 30 cases. Modernized old country house, with ample accom. and large garden; e.l.; all in good order. Price for f'hld. £2,500. Prem. £1,500.

16. DERBYSHIRE.—PARTNERSHIP.—A half share in a very sound panel and club practice, producing £3,200 p.a. Panel of over 3,000. Fees 3/6 to 5/-, medicine extra. Expenses small. Modern house, in good order, with pleasant garden. Garage. Price for freehold £1,500, part on mortgage. Premium £3,200, half down and balance by instalments over 4 years.

17. LANCS.—In a rapidly growing good-class suburb of large town (pop. nearly 200,000), a very old-estab. PRACTICE, held by Vendor over 30 years, and averaging about £900 p.a., including Union (£80, with prospect of increase shortly) and panel of nearly 1,000. There is a surgery in centre of town to which bulk of practice and panel work is attached. Private residence contains 2 reception, 3 bedrooms, bathroom, etc., and small garden. Both Vendor's properties. Price £1,750, £900 on mortgage, or would be rented. Prem. 1½ yrs ' pur.

18. [illegible] old-estab. Country PRACTICE, situated in [illegible] d averaging £700 p.a., including Union [illegible] oducing £450. Nearest opposition 3½ miles. Railway station 2 [illegible] House stands in own grounds of 1½ acres, with tennis court, garage, etc., and contains surgery, 3 reception, 5 or 6 bedrooms, bathroom (h. & c.). Electric light plant installed. Vendor's freehold, price £2,500, all of which could remain on mortgage if wished. Premium £1,050.

19. MANCHESTER.—Rapidly developing outlying suburb. Good middle- and working-class PRACTICE, increasing and producing for the last 12 months over £1,500. Panel of 700. Fees from 3/6. Particularly good house, specially built, and containing 3 reception, 5 bedrooms, etc. Electric light. Garden. Garage. Price £3,550, part on mortgage. Premium £2,250.

20. ESSEX COAST.—FAVOURITE RESORT.—PARTNERSHIP.—A one-third share to commence with in an old-established middle-class Practice. Average income of about £2,800. Panel of 600. Visits 4/6 to 21/-. Little midwifery. Suitable accommodation can be obtained. Premium 2 years' purchase.

21. BEDFORDSHIRE.—Small Country PRACTICE, at present producing at the rate of £400 p.a., but offering good scope. Fees 3/6 to 10/6, medicine extra. Good house, with 2 reception, 6 bedrooms, etc. Separate entrance to professional rooms. Can be rented on lease. Premium £250, or practice and house will be sold for £1,050.

22. SOUTH COAST.—FAVOURITE HOLIDAY RESORT.—Well-established non-dispensing PRACTICE. Average income about £1,100, including panel of 1,200. Consultations 2/6 to 10/6, visits 3/6 to 21/-. Practically no midwifery. Very good house, in best position on sea-front. Price for leasehold (with 20 years to run at a ground rent of £4 p.a., and renewable) £2,250. Premium £1,800.

23. KENT.—COAST TOWN.—Well-established mainly industrial PRACTICE. Steady average income of over £1,500. Panel of 1,350. Advice and medicine mainly 3/- and 5/-, and a few at 7/6; visits and medicine from 3/6 to 21/-. Convenient house, with 5 bedrooms. Rent on lease £100 p.a. Premium 1½ years' purchase.

24. NEW ZEALAND (North Island).—Increasing Town (pop. 2,500, with further 6,000 in district) amidst beautiful surroundings 30 miles from large city, on main line, well-established PRACTICE, producing £1,150 for last financial year, including £100 from Lodges. Consultations 10/6. Midwiferies 5 gns. Two opponents. Very good Bungalow residence, with ample accommodation and ½-acre of garden. Garage. Rented on lease or can be bought. Premium £1,000. Purchaser should have fair knowledge of surgery.

REQUIRED.—Experienced ASSISTANT, with London qualifications, for Town Practice in Suffolk. Unmarried, aged 25 to 30. Must have held Hospital appts. Good salary, and prospect of partnership later.

REQUIRED.—Indoor ASSISTANT (or outdoor by arrangement) for Country Practice in Suffolk. Must be English, and pref. Bart's man. Salary £300 p.a. indoor, and equivalent outdoor.

Full Schedule of Terms and Conditions will be forwarded on application.

rinted and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

AN IMPORTANT "CIBA" BRAND SPECIALITY

ATOQUINOL

(allyl ester of phenylcinchoninic acid)

INDICATIONS
Gout acute and chronic, rheumatic affections, uric acid diathesis, arthritis, migraine, sciatica, lumbago, etc.

PACKAGES
Atoquinol Tablets, 4 gr. (Tubes of 20 and bottles of 100 and 500).
Atoquinol Ointment, 20 per cent. for local application (Tubes of 30 grm.).

Atoquinol possesses many advantages over phenylcinchoninic acid, the chief being its low melting point—36°C. in comparison with 212°C. for the acid. It has no known incompatibles and acts in comparatively small doses as a most active uric acid eliminant.

❖ ❖

The following tables are extracted from an article published in the *Schweizerische Medizinische Wochenschrift*, by Drs. Uhlmann and Burow:

MEAT DIET (WITH PURINS)

In 24 hours	Without Treatment	Atoquinol	Phenylcincho-ninic Acid
Urine	3930 c.c.	3345 c.c.	3450 c.c.
Uric Acid	2.03 grm.	3.01 grm.	2.63 grm.

VEGETARIAN DIET (WITHOUT PURINS)

In 24 hours	Without Treatment	Atoquinol	Phenylcincho-ninic Acid
Urine	3550 c.c.	3515 c.c.	3515 c.c.
Uric Acid	0.91 grm.	2.20 grm.	1.28 grm.

COMPARATIVE TESTS

Daily Uric Acid Elimination	Atoquinol (oral)	Atoquinol (cutaneous)	Phenylcin choninic acid (oral)	Piperazine (oral)
	11.92 grm.	10.08 grm.	10.92 grm.	7.68 grm

It will be seen from the above tables that the daily elimination of uric acid is greater when Atoquinol is used than with the phenylcinchoninic acid. Also in the third table it will be noticed that the cutaneous administration of Atoquinol by means of the ointment is most effective in causing an active elimination of uric acid

❖ ❖

In an article in *The Lancet*, May 12th, 1928, on "The Treatment of Toxic Peri-Arthritis," the author refers particularly to the value of Atoquinol in fairly large doses (six tablets per diem) for a long period in such cases. It was given in periods of three days on and three days off with large draughts of water. The author states that in the course of four years in 87 cases treated he has never seen Atoquinol give rise to any untoward symptoms.

❖ ❖

In the *British Medical Journal*, January 7th, 1928, a correspondent states that he has never found any trouble or discomfort to occur after the taking of allyl ester of phenylcinchoninic acid.

You Can Trust Your Own Judgment

OBSERVE the character and composition of Agarol Brand Compound, consider the purpose and proportions of each of its constituents; *then* try it in some case of chronic constipation that has failed to respond to other lines of treatment—*and note the results!*

The remarkable welcome Agarol Brand Compound has received from physicians the country over, and the extent to which it has superseded ordinary laxative measures, tells in no uncertain way what their judgment has been — how trustworthy they have found it.

AGAROL Brand Compound, the *original* Mineral Oil—Agar-Agar Emulsion, has these special advantages:

Perfect emulsification; stability; pleasant taste without artificial flavouring.

Freedom from sugar, alkalies and alcohol; no contra-indications; no oil leakage.

No griping or pain; no nausea or gastric disturbances; not habit forming.

RHEUMATIC DISORDERS

THE AUTO-CONDENSING THERMAL COUCH

(Patent No. 248190)

FOR THE

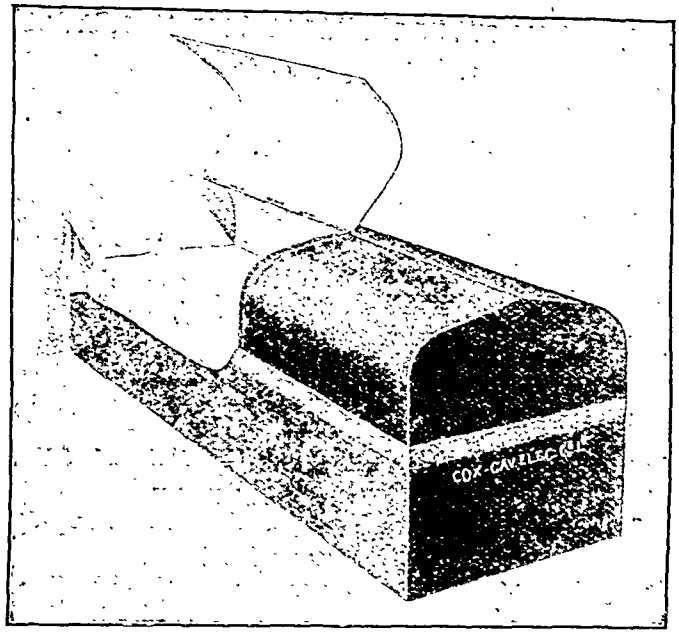
PYRETIC TREATMENT of RHEUMATISM & ALLIED DISORDERS

The most rational and successful method of treating these complaints.

THREE MODELS

Upkeep Cost Nominal.

Heated by Gas or Electricity.



Please write for booklet, fully illustrating and describing the essential principles of this remarkable apparatus.

RECOMMENDED:

"The Pyretic Treatment of Rheumatism and Allied Disorders" (1928)

By Percy Wilde, M.D.

Post free 4s. 6d.

(See many eulogistic Press notices.)

Copies of unsolicited testimonials as to results obtained will be gladly furnished on request.

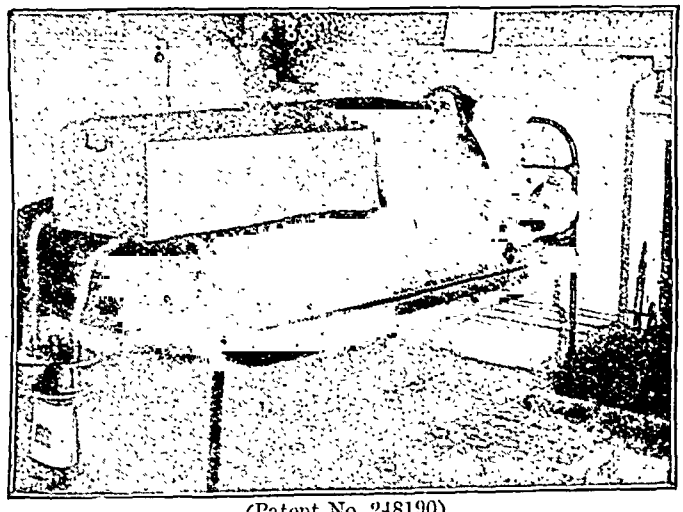
NOTICE

Owing to the increasing number of these apparatus which are being installed in various parts of the country we shall be pleased to forward the names and addresses of institutions and medical practitioners who are specialising in this treatment to any registered medical practitioner who would like to have this information. The results of treatment are so satisfactory that the extension of special centres is proceeding rapidly, and every hospital and municipal clinic should have one or more baths installed.

THE AUTO-CONDENSING MOIST AIR BATH

THIS APPARATUS IS NOT EXPERIMENTAL.

THE METHOD HAS BEEN TRIED EXTENSIVELY FOR TWENTY YEARS WITH EXTRAORDINARILY SUCCESSFUL RESULTS.



THE ELIMINATION OF LACTIC ACID FROM THE TISSUES IS REMARKABLE AFTER A FEW APPLICATIONS.

TEST CHARTS ARE SUPPLIED TO RECORD DEGREE OF REACTION.

THIS BATH MAY BE HAD ON HIRE IF DESIRED.

(Patent No. 248190)

For the PYRETIC TREATMENT of GOUT, RHEUMATISM, and ARTHRITIS—NON-AMBULATORY CASES.

The whole apparatus is self-contained. No plumbing required. Entirely noiseless. Infinitesimal cost for upkeep. Can be used on any bed. Boiler can be electrically heated if desired.

SECURE ACCURATE ABDOMINAL SUPPORT & COMFORT FOR YOUR PATIENTS BY RECOMMENDING THE

"ROSE CORSET-BELT"

EXTRACT FROM THE "BRITISH MEDICAL JOURNAL," DEC. 10th, 1927—
"Visceroptosis is the cause of so much discomfort and ill-health ... and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition.... MADAME ROSE has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

Please note new address.

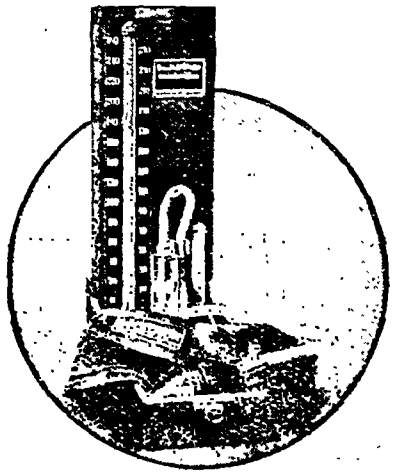
MacKENNA'S DISEASES OF THE SKIN

¶ *"Dr. MacKenna has produced a textbook well above the average—thorough, practical, sound, and easy to read—which may safely be commended both to students and practitioners. There are no fewer than thirty-six coloured illustrations in this edition, mostly from photographs . . . they form a most notable improvement on the former edition."*—BRITISH MEDICAL JOURNAL.

7 & 8, Henrietta Street, Covent Garden, London, W.C.2.

TEN TIMES TEN THOUSAND Baumanometer users throughout the world and thousands of users in England, including many of our foremost medical men and institutions, can testify to this statement. Practically all of these used some other instrument, usually the aneroid or spring type before they purchased their Baumanometer. Why the change? Because Accuracy, Simplicity and Reliability, the essential requirements in bloodpressure apparatus, are pre-eminent in the Lifetime Baumanometer. Individual calibration, total absence of mechanical adjustments, and the finest craftsmanship throughout, backed by a written guarantee against glass breakage and defects, for your lifetime, assure these features. You certainly couldn't expect more—and shouldn't be satisfied with less.



The subject of bloodpressure in all its phases is important enough and you use the apparatus frequently enough to have the very best. Possession of a Lifetime Baumanometer secures perfect, uninterrupted bloodpressure service for your lifetime.

A demonstration at your surgical instrument dealer's store will convince you.

THE NEW

Lifetime Baumanometer

STANDARD FOR BLOODPRESSURE

OBTAINABLE FROM ALL DEALERS,
OR FROM THE BRITISH DISTRIBUTORS:

HAWKSLEY & SONS, Ltd., 83, Wigmore St., London. W. 1

KERASOL for gall-bladder visualisation always in stock.

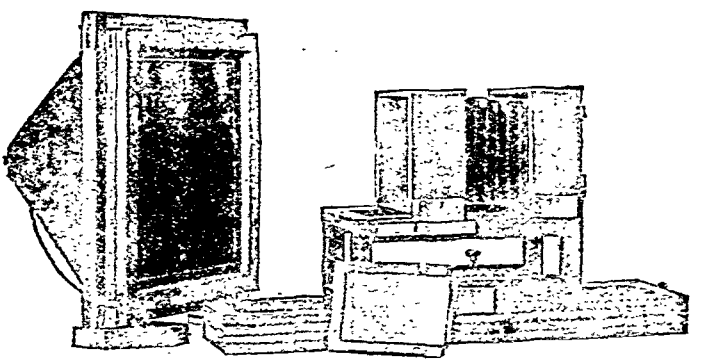
"Kodak" X-Ray Reduction Camera



A simple and solidly built camera.

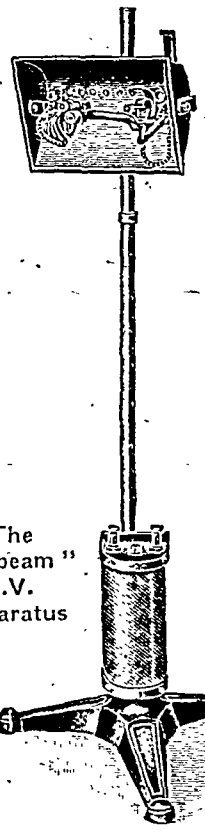
Reduces negatives of any size (up to 17 x 14 ins.)

Suitable for making bromide prints or transparencies of $6\frac{1}{2}$ x $4\frac{3}{4}$ size or smaller and lantern slides.

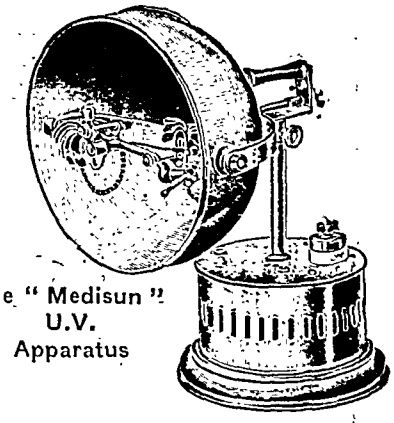
An automatic focussing scale makes the "Kodak" Reduction Camera exceedingly simple to operate.

Kodak Limited, (Medical Dept.),
Kingsway, London, W.C.2

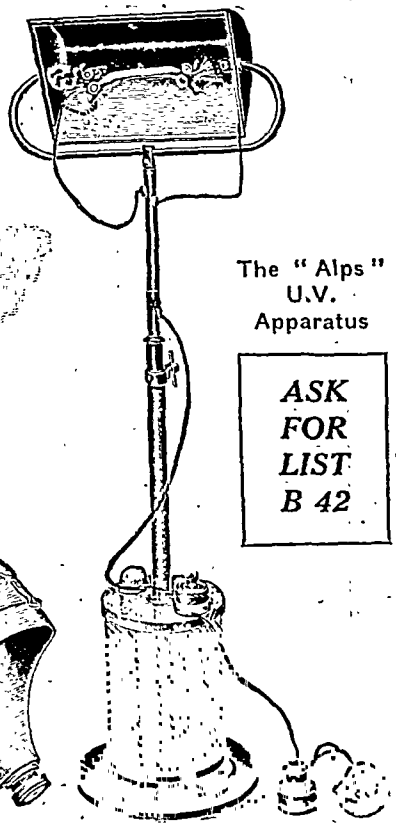
ULTRA VIOLET LIGHT



The "Medisun" U.V. Apparatus



The "Sunbeam" U.V. Apparatus



The "Alps" U.V. Apparatus

The models illustrated provide at economical cost a highly efficient source of Ultra-Violet Radiation. Widely approved by the Medical Profession on account of their simplicity and dependability, and 100% British.

ASK FOR LIST B 42

THE "MEDISUN" U.V. APPARATUS

Quartz Mercury Vapour Type.

Designed for whole body or local applications. Suitable for general practitioners, or for use in the homes of private patients.

PRICE, for use on direct current - £10
PRICE, for use on alternating current - £18

"SUNBEAM" U.V. APPARATUS

Designed for Home Use, the Quartz Mercury Vapour Burner is less powerful than our other Models and consumes less current.

PRICE, for use on direct current - £15 10s.
PRICE, for use on alternating current - £25

THE "ALPS" U.V. APPARATUS

Designed for Home or Professional use. Fitted with standard size Quartz Mercury Vapour Burner.

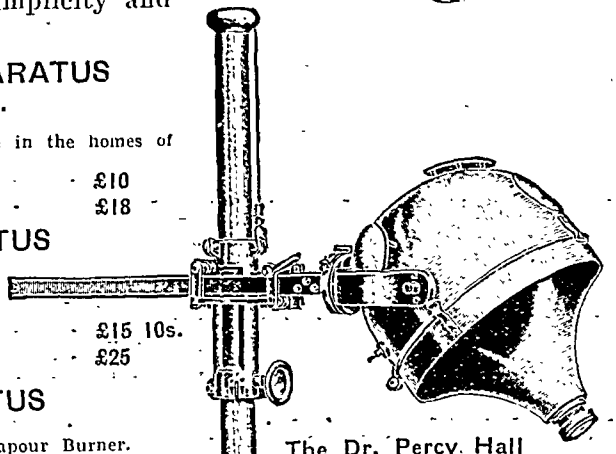
PRICE, for use on direct current - £25
PRICE, for use on alternating current - £41

THE DR. PERCY HALL U.V. APPARATUS

(Dual Purpose Model)

Provides in a single apparatus the means of applying Ultra-Violet Radiation either generally, locally, or internally by quartz applicators or specula. Acknowledged to be the most perfect type yet designed.

PRICE, for use on direct current - £38
PRICE, for use on alternating current - £53

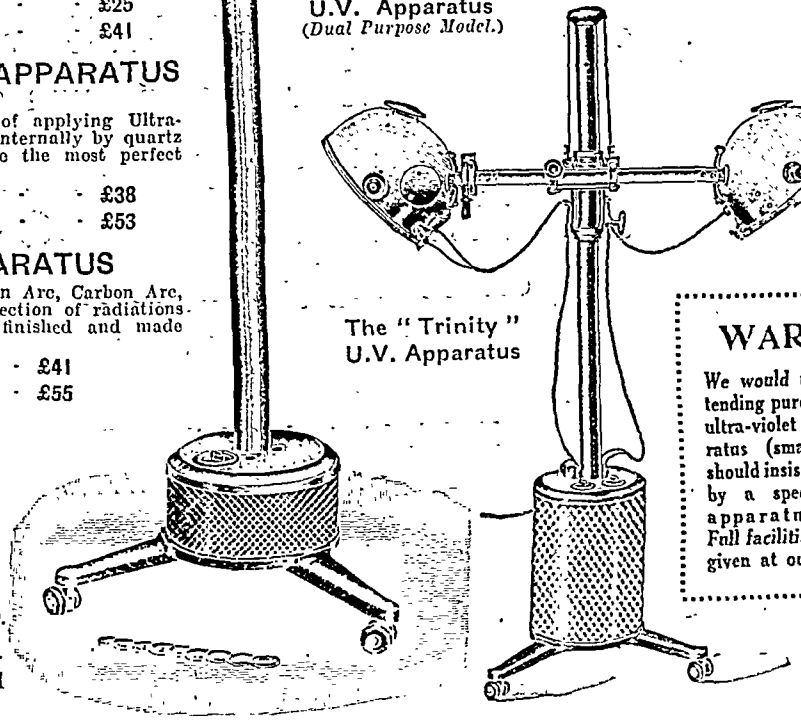


The Dr. Percy Hall U.V. Apparatus *(Dual Purpose Model.)*

THE "TRINITY" U.V. APPARATUS

Designed to provide the radiation of Tungsten Arc, Carbon Arc, and Mercury Vapour Arc, so providing a selection of radiations at the will of the operator. Handsomely finished and made throughout in our own London Works.

PRICE, for use on direct current - £41
PRICE, for use on alternating current - £55



The "Trinity" U.V. Apparatus

WARNING

We would urge that intending purchasers of any ultra-violet light apparatus (small or large) should insist on examining by a spectroscope the apparatus concerned. Full facilities for this are given at our showrooms.

The NEW U.G.B

Washed & Sterilized

Will be available from

THE introduction of the "washed and sterilized—ready for use" medical bottle is yet another achievement accomplished by the United Glass Bottle Manufacturers, Ltd., in the service of the chemist and druggist.

The washing process is the severest test that can be given, and automatically sorts out any bottles that are not thoroughly annealed.

The special fibre cartons in which they are packed also make them more convenient in use and storeage. They are a boon to every busy dispenser.

UNITED GLASS BOTTLE MANUFACTURERS · LIMITED

The biggest manufacturers of bottles and glass containers in Europe.

40/43, NORFOLK STREET, STRAND, LONDON, W.C.2.

Telephone: CENTRAL 8080-8089 (10 lines.)

Radiograph of Normal Colon

Radiograph of marked Ptosis associated with Chronic Constipation

Intestinal stasis, according to a world-famous surgeon, "is the cause of all the diseases which we have acquired as the result of civilization."

"CHRISMOL"
Liquid Paraffin

For the Rational Treatment of Constipation and Stasis by Lubrication.

Unirritating and universally applicable.
Does not interfere with digestion or absorption.
Effectively overcomes mechanical friction from hardened fæces.
Does not cause griping or gaseous distension.
Continued use does not produce "habit," lead to chronic gastro-intestinal catarrh or lose its effect as purgatives are liable to do.

"Chrismol"

The Ideal Lubricant

Perfectly pure and innocuous.

Conforms to higher standards than those of the B.P.

Viscosity determined at body-temperature to produce maximum lubricating effect.

Tasteless, colourless, odourless.

Descriptive literature and a clinical trial sample will be sent post free to members of the medical profession.

Allen & Hanburys Ltd. BETHNAL GREEN, LONDON, :: E.2.

SULPHAQUA

LARGELY AND SUCCESSFULLY PRESCRIBED IN

Skin Diseases, Rheumatism, Gout, Neurasthenic : : Conditions in Arthritic Subjects, Etc. : :

And as a valuable addition to the Inunction TREATMENT OF SYPHILIS with Mercury.

Employed in BATH and TOILET BASIN.

Possesses powerful Antiseptic, Antiparasitic, and Antalgic properties. Relieves intense Itching and Pain, is WITHOUT OBJECTIONABLE ODOUR, and does not blacken the bath enamel. Recommended for the Skin and Hair. Especially useful in the treatment of Acne and Seborrhœa of the Scalp. Largely used in dermatological practice.

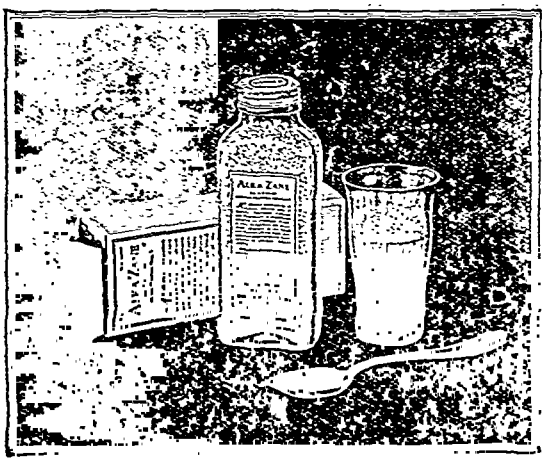
In Hyperchlorhydria



A pleasant, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium in physiologically correct proportions.

and other conditions of gastric over-acidity, Alka-Zane will afford prompt relief from distressing symptoms and restore normal alkaline balance.

Diuretic and antacid, Alka-Zane is indicated wherever the alkali reserves are unduly depleted, as in intestinal disturbances, rheumatic affections and certain anaphylactic manifestations.

The Original & Standard
Emulsion of Petroleum

Bronchitis, Sub-acute and Chronic

There is a vast amount of evidence of the most positive character proving the efficacy of Angier's Emulsion in sub-acute and chronic bronchitis. It not only relieves the cough, facilitates expectoration, and allays inflammation, but it likewise improves nutrition and effectually overcomes the constitutional debility so frequently associated with these cases. Bronchial patients are nearly always pleased with Angier's Emulsion, and often comment upon its soothing, "comforting" effects.

Pneumonia and Pleurisy

The administration of Angier's Emulsion during and after Pneumonia and Pleurisy is strongly recommended by the best authorities for relieving the cough, pulmonary distress, and difficult expectoration. After the attack, when the patient's nutrition and vitality are at the lowest ebb, Angier's Emulsion is specially indicated because of its reinforcing influence upon the normal processes of digestion, assimilation, and nutrition.

ANGIER CHEMICAL COMPANY, LIMITED, 86, Clerkenwell Road, London, E.C.1

Disturbances of Menstruation & the Menopause

The close association between the efficient action of the ovaries and the blood calcium index, provides a good reason for the administration of Kalzana in these cases. The chemical composition of Kalzana, calcium-sodium-lactate, is unique, and the special feature of the sodium element is that it raises the blood alkalinity, thereby promoting the retention of the calcium constituent.

Recent clinical notes state:

"I tried Kalzana on a patient who was suffering from anaemia due to disorder of menstruation (Menorrhagia). I obtained the most excellent results with it. The patient regained her original health and the menstrual period was regulated."

"I have now had three patients on Kalzana, all for menorrhagia, and it has benefited all three. One of the three also had acute dysmenorrhoea; this is cured apparently."

Kalzana is supplied in a convenient tablet form, is free from harmful by-effects and is pleasantly flavoured. In air-tight packets at 2/9 and 4/11.

Kalzana

Made by A. WULFING & CO., Amsterdam, Holland.

Supplies for your own dispensing, and for Hospitals, Sanatoria, etc., are available at 15/- per 1,000 tablets. Adequate samples for clinical trials, sent with pleasure, upon request.

The Importance of Symptomatic Relief

in

Urinary Tract Infections

The value of immediate relief from the distressing symptoms of infections of the urinary tract following the administration of Caprokol is appreciated by the physician and patient alike.

Caprokol treatment insures hours of continuous sleep (unbroken by the necessity for frequent micturition), cessation of pain, subsidence of fever, increased appetite, marked improvement in general health, and the establishment of a state of ease and comfort.

Although the above are of the utmost importance in the mind of the suffering patient, the effect of Caprokol therapy does not end with symptomatic relief; in most cases it goes on to the logical conclusion—the complete disinfection of the urinary tract.

Ca.(12)

For Colds, Influenza, and Pneumonia

S. U. P. 36

Intramuscular injections of S.U.P. 36 should be given in the treatment of colds, influenza, broncho-pneumonia, pneumonia, asthma, and in inflammatory and septic conditions generally.

Remarkable success has attended the use of S U.P. 36, and clinical evidence shows that it will cut short a cold in the head, if injected sufficiently early; it will enable an influenza patient to resume work after two days in some cases; it will check an attack of acute tonsillitis, and, in pneumonia, it will reduce the period of the disease very considerably.

S.U.P. 36 is a complex organic substance belonging to the class of symmetrical ureas. It is non-toxic and is soluble in water. It is issued in aqueous solution in ampoules of 1 c.c. ready for intramuscular injection.

Dimol Dosage

Ehrlich, in his search for a destroyer of the *Spirochaeta pallida*, enunciated his maxim of "Therapia sterilisans magna," and fixed a very large dose of salvarsan as the only practicable one to clear the blood of the parasite.

Similarly we submit that the entire flora in the fluid portion of the intestine can be completely sterilized by the method of Dimol Duodenal Lavage, the technique of procedure in which we shall be pleased to send to any member of the profession on request.

It is often inconvenient, inadvisable, or unnecessary to effect complete sterilization; but, on the other hand, it has been frequently brought to our notice that, owing to its guaranteed bactericidal strength of 35 times that of pure carbolic acid, it is still prescribed timidly in many cases, through caution or lack of faith in its guaranteed non-toxicity. The one pulverette only with each meal, as often prescribed, is not a sufficient dose for the destruction of the countless and hourly-changing bacteria of the gastro-intestinal tract.

The usually effective dose for adults is three immediately before or after each meal—before, if ingestion after meals produces eructation—but in chronic cases of constipation, colitis, "rheumatism," etc., this number should be increased to four, until diminished gas and fermentation symptoms indicate that the proteolytic bacteria are reduced to harmless numbers, and the tissues show unmistakable evidence that the circulation is recovering from the daily flood of toxin absorption.

Samples and Literature will be sent on application to the

OVALTINE

PHOSPHORUS IN NEURASTHENIA

Although it is realized that much difference of opinion prevails in medical circles as regards the therapeutic value of phosphorus, it is not illogical to claim that where the element is indicated, as in the neurasthenias, its tonic and restorative effects are more likely to be produced from natural phosphorus nutrients, such as those in "Ovaltine," than from medicinal products.

In the majority of cases in which "Ovaltine" has been prescribed for its "phosphorus" effect—that is, for its tonic and restorative effect upon the nervous system—the results of its administration have been gratifying in the extreme.

"Ovaltine" has been used with marked success in neurasthenia of the type known as cerebral neurasthenia, or psychasthenia, a variety of which is induced by excessive mental labour, or by worry, anxiety, or nervous strain.

The delicious flavour of "Ovaltine" renders the product acceptable even to the most fickle or jaded palate, while its exceptional nourishing qualities exert a profound influence for good health.

A liberal supply for clinical trial sent free on request.

Coated Tongue and Toxemia

Coating on the tongue consists of epithelial cells, molds, yeast, and many bacteria, some highly virulent. Normally the saliva prevents growth of the latter. If the resistance of the blood is lowered, the saliva loses its germ-destroying and inhibiting power. A tongue coating appears.

In the constipated colon, putrefactive bacteria produce highly active poisons such as skatol, indol, etc. These enter the blood, lower its resistance, and thus weaken all fluid secretions such as the saliva. No wonder 85 per cent. of all sick people have coated tongues. Constipation is almost universal among the sick.

If the tongue indicates toxemia, prescribe Nujol—the safe and effective treatment. Many intestinal toxins are themselves absorbed by Nujol.

Nujol
REGISTERED TRADE MARK

Once absorbed by Nujol, intestinal toxins cannot be absorbed by the system, as Nujol itself is non-absorbable.

VITAMALT

A Valuable Vitamin Food

FOR INFANTS, CHILDREN AND ADULTS

Rich in essential Vitamins A, B, C, & D

VITAMALT is a scientific preparation containing the finest Malt Extract of high diastatic value, with selected ingredients rich in Vitamins. It is a well-balanced food that ensures an adequate supply of Vitamins A, B, C, and D, and corrects all ailments arising from deficiency of these vital factors. There are many people who are unable to take Cod Liver Oil on account of its oily nature and fishy taste. To such, Vitamalt will prove a boon in supplying the Vitamins A and D, upon which the value of Cod Liver Oil depends.

The perfectly filled Toast Rack holds only "Ryvita Crispbread"

RYVITA CRISPBREAD — the wonderful daily bread of Sweden—is made of rye and nothing but rye, the only cereal from which the true "crispbread" can be made.

Many thousands of British doctors and dentists recommend "Ryvita" and use it in their own homes as a veritable bread of life and health.

The enthusiastic welcome and instant adoption of "Ryvita Crispbread" by food experts and the public has led to the astonishing success that has by now firmly established "The Ryvita Crispbread Habit" in our country.

"Ryvita," for every bread use, helps to make indigestion, constipation, malnutrition and obesity unknown. Yet . . . so unique is this wonderful bread that it is almost impossible, even when dieting, to eat too much of it.

Try "Ryvita" with butter and marmalade and you will discover an almost unbelievable improvement on your old time breakfast toast. "Ryvita" makes you fit and keeps you slim.

Sold by all good grocers and stores at 1/6 per (40-50 slice) 1-lb. carton; ½-lb. 10d.

(*Aesculapius*)

TREATMENT OF SPRUE

When it became known that Liver Extract was a specific for Pernicious Anæmia, it was only natural that thoughts should turn towards the use of liver in diseases manifesting themselves in similar ways. Such conditions are Sprue and Anæmia due to the tapeworm *Dibothriocephalus latus*. Clinical trials of liver in Sprue are extremely favourable, particularly when the blood picture simulates that of Pernicious Anæmia.

HEPATEX

is now recognized to be the most convenient form of

LIVER EXTRACT

for oral administration. Prepared in accordance with a special process evolved in Evans' Biological Institute from fresh and healthy livers, it is ensured that the whole of the therapeutic principles are contained in the final product. It is a palatable liquid extract which can be taken undiluted in one drachm doses, each drachm containing the equivalent of 2 ozs. of fresh liver.

Supplied in 4-oz. bottles containing sufficient for 8 days' full treatment.

Price 12/- per bottle.

Prepared at Evans' Biological Institute, Runcorn.

EVANS SONS LESCHER & WEBB LTD.

56, Hanover Street, LIVERPOOL. DUBLIN. 50, Bartholomew Close, LONDON, E.C.1.

CHATELAIN'S REMEDIES

URODONAL

Arthritism, Rheumatism, Gout, Gravel, Stones, Arterio-Sclerosis, Pains, Acid Dyspepsia, Etc.

5/- and 12/- per Bottle.

JUBOL

"Re-educates" the Intestine.
Constipation, Enteritis, Hæmorrhoids, Flatulency, Etc.

Jubol contains biliary extracts (whose stimulating action on the muscular coating of the intestine is well known); and of the active principles of all the glands (the secretions of which assist in the process of intestinal digestion); the whole being associated with agar-agar and iodized fucus in order to facilitate the evacuation of hard matter.

3/- per Box.

JUBOLITOIRES

A new form of Suppository, composed of "Eumarrol" (a new extract of horse-chestnut), "Resorthan" (a new salt of resorcin and of bi-iodized thymol), belladonna and hyoscyamus, associated with "Gerastyl" (extract of Geranium Maculatum) and adrenaline.

The use of JUBOLITOIRES is indicated in Hæmorrhoids, Anal Fistula, and all conditions of congestion of the lower bowel. The suppositories effectually remove painful symptoms, check Hæmorrhage even in its severest forms, and assist in restoring the normal functions of the bowel.

Price 3/- per Box.

GLOBÉOL

Anæmia, Convalescence, Tuberculosis, Neurasthenia, Rapid Growth, Scrofula, Nervous Exhaustion, Brain-Fag, Nervous Diseases, Insomnia, Tabes, Etc.

Globéol is composed of total extract of the blood serum, and of red corpuscles (after removal of all useless tissue from the latter). It also contains colloidal iron and manganese.

Globéol is much more active than raw meat, kola, Fowler's solution, hæmoglobin, ferruginous preparations, and tonics. A course of Globéol increases nerve power, and restores energy, vigour, and elasticity to the nerves. It is a wonderful heart tonic.

3/- per Bottle.

SINUBÉRASE

A Scientific depurative agent for auto-intoxication originating from the Intestines. Enteritis, Dyspepsia, Infectious Diseases, Gastric Disorders, Diarrhœa, Arterio-Sclerosis, Typhoid Fever, Dermatoses, Carbuncles, Etc.

Sinubérase is composed of super-active lactic ferments, associated with the protoplasma of beer-yeast and with the active principles of malt. It is a highly active agent, inasmuch as it combines the three kinds of ferments that act on special portions of the digestive tract.

Sinubérase ensures a healthy condition of the digestive tract: it prevents putrefaction, carries away toxins, cleanses the tongue, and maintains the normal condition of the intestines.

3/- per Bottle.

Note for the Medical Profession

A Powerful Non-Toxic Germicide

EFFECTIVE coal-tar antiseptics are severely restricted in clinical use by their damaging action on tissues. Except in a few instances, their usefulness lies mainly in the disinfection of utensils, etc.

An antiseptic of equal germicidal efficiency, and without destructive action on tissues, could be employed in clinical practice for purposes and with effects hitherto unprecedented. *MONSOL IS SUCH AN ANTISEPTIC.*

GERMICIDAL EFFICIENCY

Tested in the presence of organic matter, the germicidal efficiency of Monsol for fæcal bacteria greatly exceeds that of other representative antiseptics. The selective action of Monsol classes it apart from any antiseptic of similar origin, in that its efficiency is greatest for the Gram-positive cocci. Monsol kills the Streptococcus Pyogenes in a dilution *more than* 10 *times greater* than phenol or lysol.

TOXICITY

Monsol is absolutely non-irritant to the skin. Effective solutions of Monsol can be applied to mucous membranes. Large amounts of pure Monsol given by the alimentary tract to animals have failed to demonstrate any poisoning action. Monsol has been given intravenously to animals in amounts equivalent to no less than 1-60oth of the total blood volume with only transient ill-effects. No other antiseptic exists which possesses these properties.

FRAGMENTS OF THE WORKSHOP OF A KELTIC PIONEER ENAMELLER.—The art of enamelling was practised by the ancient Egyptians and Assyrians, who applied it chiefly to pottery and brick; other peoples of antiquity, including the Greeks and Romans, decorated their jewellery in this fashion. The Kelts seem to have introduced improvements in the method of applying enamel and to have extended its uses. It is believed that the Kelts, unable to procure coral in sufficient quantity, set up workshops and produced red enamel as a substitute Red was the only colour employed at first, and enamel of this tint is found to have been applied to precisely the same uses as coral. The remains of actual furnaces have been found, together with large quantities of debris, such as parings of metal, charcoal, quartz, crucibles and tools such as those here reproduced on the right. In addition to bronze prepared for receiving the vitreous colours, enamelled, domed discs were discovered (like those on the left) which are shown also *in situ* on the portion of harness (from Alsace). Enamelled discs appear to have been an improvement invented by the Kelts of Gaul to take the place of the flat-headed iron nails, covered with enamel, which had hitherto been the vogue.

A British Medical Association Lecture
ON
CEREBRAL TUMOURS.

DELIVERED BEFORE THE SHEFFIELD DIVISION, NOVEMBER 9TH, 1928,

BY

H. S. SOUTTAR, C.B.E., D.M., M.CH., F.R.C.S.,
SURGEON, LONDON HOSPITAL.

CEREBRAL tumours are unique in the nature and the variety of the symptoms they produce, in the diagnostic problems they present, and in the difficulties which must be overcome by the surgeon who endeavours to approach them. Moreover, they are by no means uncommon in every class of practice, and the general physician, the ophthalmic surgeon, and the aural specialist must all be prepared to meet them; they are more destructive to the patient than any other class of tumour, and they affect personality in a manner which must always arrest our interest and arouse our sympathy. There can be few conditions which make a more widespread appeal.

In the short time at my disposal I propose to glance at cerebral tumours from three points of view—those of the physiologist, the physician, and the surgeon—and to reply briefly to three questions: How do these tumours produce symptoms? What symptoms do they produce? How may they be approached? Naturally a full reply to these questions would involve an elaborate treatise, but even their brief consideration gives some insight into the problems which confront the cerebral surgeon.

THE PRODUCTION OF SYMPTOMS.

The brain differs from all the other organs of the body in the fact that it is enclosed in a rigid case, which entirely modifies the conditions of its circulation, and in the existence within and around it of a secondary and independent circulation, that of the cerebro-spinal fluid. Tumours produce their effects not, as might be supposed, from the pressure they exert on the cerebral tissue, but from the interference they produce with the arterio-venous and the cerebro-spinal circulations. Let us first consider the latter.

The cerebro-spinal fluid is continuously secreted by the choroid plexuses, chiefly in the lateral ventricles, and from these it flows through the foramina of Monro into the third ventricle, from which it is conveyed by the aqueduct of Sylvius to the fourth ventricle, escaping by the foramina of Luschka and Magendie into the subarachnoid space, to be finally discharged by the Pacchionian bodies into the superior longitudinal sinus. A tumour involving the cerebral hemispheres may grow to a huge size without ever affecting this circulation. On the other hand, even a small tumour situated in the interpeduncular space, in the corpora quadrigemina, or at any point below the tentorium, may obstruct the flow, and by producing a secondary hydrocephalus may cause a sharp rise in the intracranial pressure. Such a rise in pressure is associated with general symptoms of the utmost severity, and to this consideration alone is very largely due the contrast in immediate danger between supra- and infra-tentorial tumours. Above the tentorium the general symptoms are mild, and surgery is comparatively easy: below, the conditions are always critical, and surgical intervention will only too often be fatal. By the secondary hydrocephalus the cerebellum is forced down through the foramen magnum till it forms a cone, which may reach as low as the third cervical lamina, crushing beneath it the medulla and the vital centres it contains.

These general indications include the classical symptoms of intracranial pressure, headache, vomiting, and papilloedema. I would insist, however, that only in a secondary sense are these the symptoms of an intracranial tumour, and that every effort should be made to effect a diagnosis before they arise. To wait for them is as unreasonable as to wait for acute intestinal obstruction before diagnosing a tumour of the colon. When, however, these classical symptoms occur they are of great importance, and present very definite characters. The headache is constant, but with severe exacerbations. It is often severe on waking, and it is increased by anything which raises the intracranial pressure, such as exertion, excitement, or even stooping. Vomiting is also marked on rising in the morning; it is independent of food, unaccompanied by abdominal pain, not preceded by nausea, and therefore occurs as a sudden projectile act without warning. Papilloedema may be present in a severe degree before it becomes subjectively obvious to the patient in blurring of vision, but, as a rule, when it is at all marked, a careful examination of the visual fields will show some degree of contraction for small, white objects. Transient attacks of blindness may occur, but persistent diminution of vision means that atrophy has commenced, and complete recovery of visual power is then impossible. The swelling of the disc may be accompanied by retinal haemorrhages, and is generally, though not always, most marked on the side of the lesion.

Among other general symptoms are a certain loss of initiative, mental lassitude and drowsiness, attacks of giddiness, slowing of the pulse, and possibly generalized epileptiform convulsions. A transient diplopia, occurring, as it may, at a very early stage, should be regarded as a symptom of the very first importance. These are all symptoms of high intracranial tension, and as such they may appear apart from cerebral tumours in such conditions as renal disease, severe anaemia, or lead poisoning. The latter are, however, readily excluded.

It is, however, to the local effects produced by a cerebral tumour that we must direct our attention if we are to discover its precise situation. The mere pressure of a tumour on the actual cells of the brain would probably be entirely without result were it not for the interference with the cerebral circulation by which this pressure must in practice be accompanied. It is a clearly established law of cerebral pathology that congestion means irritation, and anaemia paralysis. Now the first effect of the pressure of a tumour must be interference with the venous return and congestion of the region of the brain concerned. If this happens to be the sensorimotor cortex the irritation may show itself in the production of Jacksonian fits, starting in that region of the body which the particular portion of the motor cortex supplies. As the tumour grows and the pressure increases the capillaries will be compressed, anaemia will be produced, and paralysis will replace the irritation; but, in addition to an increase in the actual pressure at any one point, we have an extension of the area involved, so that, in fact, we shall have a spreading area of paralysis surrounded by a zone of irritation. The whole effect is enhanced by the fact that every now and then an acute oedema may arise around the advancing tumour, increasing the general pressure and producing a dangerous exacerbation of the symptoms, sometimes the abrupt prelude of a fatal termination.

TUMOURS OF THE ROLANDIC AREA.

The most important portion of the cerebral cortex, from the point of view of intracranial tumours, is undoubtedly that which lies in front of the fissure of Rolando, the precentral or ascending convolution. It differs histologically from any other portion of the cortex, since here alone are found clusters of giant pyramidal cells of Betz, from which arise the great pyramidal tracts. It is essentially the final area through which the volitional control of the brain is conveyed to the muscles. It originates nothing, but it transmits movement formulae for the execution of various skilled acts, the formulae being prepared by the synthetic action of other centres—visual, auditory, sensory, or psychic. It has, in addition, the important function of inhibiting muscular tone, the muscles being thus held ready for instant response to the transmitted formulae. Its destruction, therefore, leads to a loss of volitional control and to an increase in muscular tone which hampers useful action.

In this area the different portions of the body are represented by centres arranged in a very precise manner (*Fig. 1*). At the extreme upper end commence the centres

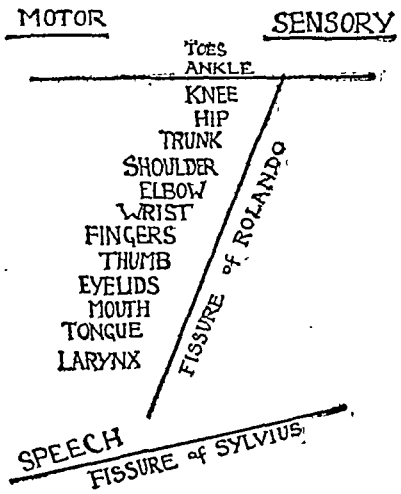

FIG. 1.

for the leg, the toes and ankle being represented actually on the mesial surface of the hemisphere. Passing downwards, the knee and hip are followed by the trunk, which lies just opposite the superior genu of the fissure. Below this come in order the shoulder, elbow, wrist, fingers, and thumb. The tongue and larynx follow. Just in front of the hand area is a special area for the control of the conjugate movements of the eyes and rotation of the head to the opposite side.

When a tumour affects this region it gives rise to symptoms, as we have already explained, by the interference with the circulation which it produces. When the pressure is slight and only congestion results, irritation is produced; when it is more severe we have anaemia and paralysis; and inasmuch as the tumour is steadily advancing there will usually be a zone of paralysis surrounded by a zone of irritation. The phenomena of irritation in this region have a very characteristic form, first described by Hughlings Jackson, and universally known as Jacksonian fits. The characteristics of these are that they start in a precise region of the body, always the same, and that they spread to other regions in a definite order, corresponding exactly to that in which the centres are arranged in the cortex. They may be preceded by twitching or tingling in the part, and they commence with a stage of tonic spasm, passing into a series of clonic jerks as the centres become exhausted. Consciousness is only lost if the convulsions become generalized. The fits may occur at any interval, from months down to minutes, and a very important feature is that they are always followed by definite weakness in the portion of the body in which the fit starts.

Cortical paralysis has equally striking features. It is essentially a paralysis of movements, and not of individual muscles, or even muscle groups. Stimulation of the centres in the motor cortex gives rise to definite movements, such as flexion of the elbow or abduction of the arm, in each of which certain muscles contract with nicely balanced force, whilst other antagonistic muscles are relaxed in suitable degree. Destruction of the centre removes from the individual the power of initiating the movement concerned, and at the same time the removal of cortical inhibition and control compels the limb to take up a characteristic attitude. Thus, in a complete hemiplegia, where the whole cortical control is removed, the arm will take up a position of adduction, with flexed wrist and fingers. The leg, on the other hand, will be adducted and extended at the hip, and extended at the knee and the ankle. In partial lesions other attitudes may be adopted. In all cases the paralysis will be accompanied by an increase in tone in the muscles and by an increase in the deep reflexes.

The growth of a tumour pressing on the motor area will therefore give rise to a characteristic clinical picture—Jacksonian fits, followed by weakness in the region of origin, and a steadily advancing paralysis. The latter spreads, as before, in accordance with the arrangement of the cortical centres, and thus presents certain peculiar features.

As an example of the mode of spread I may cite a case where the fits always started with twitching of the left thumb. After a few moments the tonic stage came on, a tonic spasm spreading successively to the fingers, wrist, and arm, and simultaneously to the left side of the face and tongue, whilst at the same time the head and eyes were forcibly turned to the left. The spasm terminated in a series of clonic jerks, and only occasionally did the fits spread to the leg, when they became general, with loss of consciousness.

Immediately in front of the precentral area lies the intermediate precentral area, in which it is probable that motion formulae are constructed and retained, and that the memory for skilled acts resides. Upon its integrity depends the accurate performance of actions which we have learnt by practice to execute with facility, whilst its destruction, especially on the left side, may abolish the possibility of such acts, although there may be no paralysis in the ordinary sense. Such a condition is known as motor apraxia. By far the most important example is in lesions of the posterior extremity of the left inferior frontal convolution in right-handed individuals, the area of Broca, in which is stored the memory of those movements involved in speech. The loss of this area makes voluntary speech impossible, although the individual may know exactly the words he wishes to use, and may be able to look them up in a dictionary. In the involvement of the area by a tumour these symptoms are diagnostic, but the area is of further importance to the surgeon, since, whenever possible, he will avoid its neighbourhood, and will plan his explorations so as to leave it intact.

Behind the fissure of Rolando lies the post-central convolution, where are grouped centres for sensory reception, roughly corresponding in arrangement with the motor centres we have just described. Injury to this area may produce in the corresponding region of the body a loss of postural sense, of localization, of touch, or of the perception of the degrees of heat and cold, and it is of diagnostic import that this loss is irregular in distribution and in the extent to which each element of sensation is affected. Irritation produces a sensation of tingling in the corresponding area, and as these sensory centres are in such close proximity to the motor centres it follows that a tumour is likely to involve both, and that tingling in a limb may be the definite precursor of a Jacksonian convulsion.

It will thus be seen that on the lateral aspect of the brain there exists a wide area interference with which produces characteristic symptoms. A tumour in this region may therefore be located in many cases with the most minute precision, but the area is of almost equal importance in the diagnosis of tumours which reach it from other regions of the brain. Thus, the first indication of a frontal tumour may be given from involvement of the motor area in its backward extension, whilst tumours of the occipital and temporal lobes may remain equally obscure until the sensorimotor cortex is affected. We have, however, another means at our disposal for the localization of cerebral tumours—in the effects which they produce upon the visual tracts—and these we must now consider.

TUMOURS INVOLVING THE VISUAL TRACTS.

The tumours of which I have so far spoken have as their chief characteristic some interference with motion. Another group, not perhaps so common, but even more fascinating in the problems it furnishes for diagnosis, interferes with vision. Visual impressions starting in the retina pass through the whole length of the brain to the occipital lobe behind. The fibres of the optic nerves decussate in the optic chiasma in such a way that the visual impressions from the visual fields on each side of a median plane are transmitted entirely to the opposite side. Through the optic tracts impulses from the contralateral fields are carried back to the external geniculate body and the pulvinar of the thalamus. From the former run tracts connecting it with the mid-brain and with the centres which control the movements of the eyes. From the latter spread out the optic radiations, looping round the descend-

ing horn of the lateral ventricle to reach their destination in the cortex of the occipital lobe. It is to this final portion of the optic path that I would for a moment direct your attention.

The optic radiations are so arranged that the upper fibres receive impulses from the upper portions of the retinae, the lower from the lower. This order they maintain right up to the point when they terminate in the cortex above and below the calcarine fissure on the mesial aspect of the occipital lobe. In relation to tumours of the occipital lobe itself this distinction is not of importance, for, as a rule, the whole visual area is involved, with resulting disturbances of vision in the contralateral visual field. These disturbances may be of two kinds—irritative or paralytic. The former are more likely to be produced by cortical tumours, and appear as flashes of light, often coloured and suggesting fireworks. Probably the fortification lines of migraine are due to vascular disturbance in this region. Deep tumours, on the other hand, produce a gradual contraction of the visual field on the opposite side, best shown by testing with small objects, white or coloured. The superficial tumours again tend to spread forwards over the cortex and to involve the lower sensorimotor areas, producing numbness in the opposite face or hand. The deep tumours tend to involve the posterior part of the internal capsule, producing sensory changes in the opposite leg. of the body and paresis in the opposite half

But to the optic radiations themselves we owe a syndrome as beautiful as any in cerebral pathology, and in the hands of Cushing they have supplied the key to what was one of the most obscure regions of the brain (Fig. 2). These

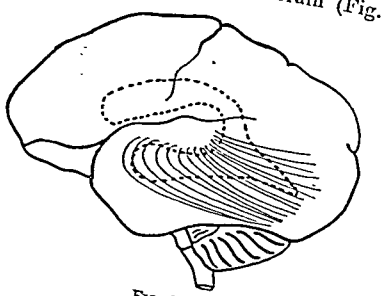

FIG. 2.

radiations as they leave the optic thalamus wind forwards, outwards, and finally backwards round the descending horn of the lateral ventricle, occupying as they do so the posterior part of the temporal lobe. Their arrangement in upper and lower groups connected with the upper and lower portions of the retinae has already been noted. A tumour, then, in the lower part of the right temporal lobe will involve those fibres which carry impulses from the opposite upper visual field, and the left upper quadrant will be blind, and we have the condition known as a left upper quadrantic homonymous hemianopia. The discovery of these quadrantic hemianopias has revolutionized localization in the temporal lobes.

It is typical of quadrantic hemianopias that the visual defect is incomplete, and it is owing to this fact that they have so long escaped attention. They can only be discovered by the most accurate and painstaking perimetry, and only at an early stage of the development of the tumour. A rough perimetry will miss them entirely, and in a late stage they will be merged in a complete hemianopia, but if found they are almost conclusive evidence of a tumour in the temporal lobe.

But the temporal lobe yields another symptom as bizarre as any in cerebral symptomatology. When a tumour involves the uncus the patient is liable to peculiar attacks, lasting for a few seconds and perhaps recurring many times in the day. In these he is overpowered by a dreamy sensation, the world seems remote, and voices sound far away. In this state he may have curious hallucinations of smell, taste, hearing, or vision. The first two are perhaps the most common, and though sometimes pleasant are usually so repulsive as to produce an expression of disgust on the face. Those of vision are very curious, and form definite pictures, such as a row of black cats or a little figure, in contrast to the visual disturbances seen in tumours of the occipital lobe. These pictures are always in the same on every occasion, and they are always in the blind portion of the visual field. The combination of a quadrantic hemianopia with uncinate attacks thus forms a very complete and exact syndrome, distinguishing sharply, when it occurs, tumours of the temporal lobe.

SURGICAL ACCESS TO THE BRAIN.

The problem of obtaining easy access to the interior of the skull has become of increasing importance with the modern demand for large openings, in which it shall be possible to replace the bone without fear of risking its vitality. The problem raises several questions, the first of which is that of access to the skull itself. It is a curious example of tradition that until quite recently it was generally believed that contact with the scalp must be maintained if the blood supply of a bone flap was to be preserved.* I have, however, demonstrated conclusively that the vascular supply of the bone and of the scalp are entirely independent, so that the scalp may be turned down freely without the slightest prejudice to the vitality of an osteoplastic flap, which derives its vascular supply entirely from its muscular pedicle. The free exposure of the skull is obviously the first stage towards easy access to the brain.

There are three primary regions from which the brain can be approached—the temporal, occipital, and frontal—and in each instance the scalp flap required presents certain peculiarities.

In the temporal region a flap of any dimensions may be formed, care being taken that the anterior portion of the incision lies well in front of the ear, so as to avoid injury to the superficial temporal artery. In this instance a great advantage is gained by first marking out the pedicle with two small incisions, one in front of, and one behind, the ear, tunnelling through with a blunt dissector in the areolar layer, passing one blade of a soft intestinal clamp through the tunnel so formed, and with it clamping the base of the pedicle. If this is done there will be no bleeding whatever from the cut margin of the flap itself, and the attention of the surgeon can thus be directed solely to preventing bleeding from the opposite side of the incision. After the incision has been made and the bleeding arrested the whole flap can be turned down as far as the clamp at its root without the division of anything except soft areolar tissue, and without bleeding from a single point.

In the occipital region the scalp can only be turned down as far as the superior curved line of the occipital bone, since below this point it is firmly attached to the muscles. If an attempt is made to raise it beyond this point the origin of the occipitalis muscle must first be divided, and the skin must then be dissected away from the muscles, to which it is united by dense and vascular fibrous tissue, and bleeding may be considerable. With the methods of approach which we now adopt we always respect this attachment, and never go beyond it. None the less we can turn down osteoplastic flaps in this region, and even remove the bone, without ever detaching the scalp from the muscles to which it so firmly adheres.

In the frontal region superb access to the bone may be obtained by very simple means. If an incision is carried boldly across the bregma, coming down just in front of the ear, it will be found that the whole of the forehead can be turned down without the slightest difficulty, even beyond the upper margins of the orbit. It is true that the anterior branch of the superficial temporal artery is divided, but the forehead has an ample blood supply apart from this. I would again point out that even in this region the vitality of the bone is in no way jeopardized, and that an osteoplastic flap consisting of one-half of the frontal bone may be formed with perfect success on the temporal muscle as a base. When the scalp flap is replaced the suture line is entirely out of sight, and the nerve supply of the forehead is still intact. I have repeatedly carried out all these procedures under local anaesthesia with a conscious patient; there has been an entire absence of

* Hunterian Lecture, *British Medical Journal*, February 25th, 1928.

either shock or pain; and in the case of the frontal flap the only additional precaution taken was to cover the patient's eyes and face with a sterile bandage.

CONTROL OF HAEMORRHAGE.

The control of haemorrhage from the scalp is a matter of the very first importance to which sufficient attention is rarely paid. Any loss of blood at this point is entirely unjustifiable and may prejudice the further stages of the operation very seriously. Bleeding from the smaller vessels is best controlled by a preliminary injection of the whole line of incision with 1/2 per cent. novocain, to which about 1 per cent. of 1 in 1,000 adrenaline has been added. At the same time it is our custom to infiltrate the whole of the subaponeurotic space in the operation area with the same solution. If this is done half an hour before the operation there will be no bleeding at all from the smaller vessels, and only the larger arteries will require attention. These may be seized in special forceps, such as those of De Martel, which grasp the whole thickness of the scalp, or they may be compressed by seizing the galea in artery forceps and drawing it over the cut area. The arteries themselves it is impossible to seize owing to the density of the tissue in which they lie. Personally I use small steel clips which are crushed with forceps on to the margin of the scalp. They hold it quite firmly without injury, they are so small that they are not in the way, and at the end of the operation they are very easily removed. In the case of the temporal flap I have already described the means by which bleeding from its margins is prevented. In the frontal flap the incision lies in a watershed area where vessels are very small, and the only two vessels which bleed are the anterior branches of the superficial temporal artery. The absolute bloodlessness of this line of incision is remarkable and a very great advantage.

DIVISION OF THE BONE.

Even when the skull has been freely exposed the actual division of the bone presents a mechanical problem of no mean order. With the old methods it involved an expenditure of time and a degree of exertion on the part of the surgeon which only too often left both patient and surgeon physically exhausted, at a moment when the real business of the operation was only about to begin. It has long seemed to me that it should be possible to cut through the skull entirely by hand if the problem could only be reduced to the terms of ordinary engineering. I have now succeeded in devising an appliance by which the skull can be divided entirely by hand with great facility and so smoothly that the operation can be easily accomplished on the conscious patient under a local anaesthetic. The appliance was specially designed for the formation of large osteoplastic flaps, and it enables the surgeon to form these with a facility, a rapidity, and a precision hitherto unapproached.

The principle on which it works is the entirely novel one of securing a steel peg in the skull at the centre of the proposed flap and using this as a fulcrum round which can turn a powerful lever carrying a cutting tool. The cutting tool is a narrow chisel such as is used by turners for parting their work, and it cuts in the skull a narrow circular channel with extreme precision. The groove is cut on a bevel, and one advantage of the method is that the bone flap can be replaced with the absolute accuracy of a ground glass stopper. Naturally so novel an instrument requires some practice before it can be used with facility, but when this is attained large bone flaps can be cut with an ease and rapidity hitherto unattained, and we have seen a four-inch flap turned down in the temporal region in four minutes without any apparent effort on the part of the surgeon.

OSTEOPLASTIC FLAPS.

Having shown the possibility of obtaining a full exposure of the skull by first removing the scalp, and having described the apparatus at our disposal for dividing the bone, I will now discuss the actual formation of osteoplastic flaps. These are required in three regions—lateral, posterior, and anterior—and as the method of formation is in each case distinct, I will deal with them separately and in this order.

Lateral approach by means of a temporal flap is the commonest mode of access to the brain. Not only is it required for the removal of tumours in the sensorimotor region and in the temporal lobe, but it is often the most convenient and effective method of obtaining decompression. A large scalp flap is first turned down, as has been already described, bleeding from the flap being controlled by a clamp across its base, and from the scalp by clips attached to its margin. The total loss of blood should be trivial, and all bleeding must be absolutely checked before the next step is taken. The scalp flap and the exposed area are carefully protected by gauze pads moist with warm saline.

The bone flap required is now marked out with a compass, and the bone is divided round three-quarters of a circle with the craniotome, the temporal muscle which is to form the hinge being carefully preserved. Elevating levers are inserted and the thin bone in the temporal fossa is cracked, when the bone flap can be turned down and out of the way. The bone usually cracks at a point half an inch or more from the base of the skull, and it is convenient to strip down the temporal muscle as far as the temporal crest and to remove the thin bone with punch forceps. In this way maximum use can be made of the opening in the skull, and if the bone is replaced the defect left at its base forms a very useful subtemporal decompression.

Posterior approach to the brain has usually been obtained by piecemeal removal of the occipital bone below the lateral sinuses, and this has been generally regarded as a region entirely unsuited to the formation of osteoplastic flaps. The situation has, however, been entirely altered by the craniotome, which enables huge osteoplastic flaps to be turned down in this region with precision and safety, affording an access to the cerebellum, the brain stem, and the occipital lobes never before achieved. At the same time the bone, in whole or in part, can be replaced with perfect accuracy and with absolute security. The effectiveness of the method can be sufficiently judged from the fact that the whole of the back of the skull, from the lambda to the foramen magnum, can be turned down in five minutes with the utmost ease, without the slightest violence, and often without any change either in the pulse rate or the blood pressure of the patient.

A scalp flap is first turned down, as we have already described, as far as the superior curved line of the occipital bone, to which it is attached. This flap should overlap the proposed skull flap by half an inch. A point is now selected about half an inch above the external occipital protuberance, and here a hole is drilled for the centre pin. The bone at this point is very thick, and it may not be necessary to drill completely through; indeed, it is an advantage not to do so, as a large emissary vein may be encountered. Should, however, bleeding occur, it is immediately stopped by the insertion of the centre pin, which is then secured in place. The skull is cut as usual, and as it is here often half an inch or more in thickness the power of the craniotome is fully demonstrated. A channel is cut which divides the thick bone completely and extends below the lateral sinus on each side. With a specially guarded chisel the extremities of this channel are extended towards the foramen magnum, when it will be found that on raising the bone the whole posterior margin of the foramen magnum is included in the fragment. Seizing the upper margin of the bone in forceps it is drawn forcibly backwards, so as to avoid injury to the medulla, and it is then turned downwards over the nape of the neck, still attached, of course, to the whole of the nuchal muscles.

The only risk in this procedure is that of haemorrhage from the large emissary vein which communicates between the torcular Herophili and the vascular diploë of the occipital bone. In raising the bone this vein is torn, and the finger of an assistant must be immediately applied to stop the haemorrhage. A small piece of muscle, cut ready for the purpose, is now applied and held in place by the finger for three minutes, when it will be found to adhere firmly and to have stopped the bleeding. Occasionally a similar but smaller vein may be torn from the superior longitudinal sinus, but it is easily dealt with in a similar

manner. There would seem to be no risk whatever of injury to the sinuses themselves.

The field now obtained is very remarkable. In the centre lies the torcular, the lateral sinuses spreading outwards on each side, whilst above these the occipital lobes are exposed to an extent of perhaps two inches. Ideal access to the cerebellum is offered, and, if necessary, the posterior arch of the atlas can be removed. But most important of all is the relaxation of the tentorium which results from the removal of its posterior support, so that it can now move upwards freely and release the pressure on the medulla. Provided there is no undue pressure on the upper chamber this may provide sufficient decompression without any opening of the dura, and in a case of midbrain tumour with secondary hydrocephalus this procedure alone was sufficient to secure permanent relief. In any case a combination of this with aspiration of the ventricles will give all the relief of tension that can be desired.

Mobilization of the tentorium, so far as I am aware, is an entirely new procedure, and it is only rendered possible by the occipital osteoplastic flap which has been described. Without the craniotome the formation of such a flap is scarcely a mechanical possibility, for it demands the clean cutting of the densest part of the skull over a very large circle. The trauma to the patient which would result from attempting to do this by any other method would be so serious as to prohibit its performance. Moreover, the flap must be turned down with great rapidity if serious haemorrhage is to be avoided from the large emissary vein, to which reference has been made. With the method here described the actual turning down of the bone flap is practically instantaneous, and in no case has the bleeding remained uncontrolled for a longer period than two seconds. I am so impressed with the value of mobilization of the tentorium that I feel that this possibility alone justifies the invention of the craniotome.

Anterior approach is rendered much easier by the frontal scalp flap, which has already been described. This places the whole of the frontal region at our disposal, and allows the formation of osteoplastic flaps on a generous scale. The thick anterior portion of the temporal muscle, the origin of which extends right up to the angular process of the frontal bone, furnishes an ideal hinge and preserves an adequate blood supply. If the craniotome is used the centre will generally be placed a little above the temporal line, and the line of division of the bone will be just above the superciliary arch and to one side of the middle line, although the latter may be crossed without risk if a really full exposure is desired.

This method of approach furnishes admirable access to the frontal lobe, and, if this is displaced, to the falx cerebri, in its anterior portion. It is, however, of still greater value in the approach which it offers to the pituitary gland. If the bone flap is properly formed it will be found that the whole of the bone overlying the frontal lobe has been removed, and that the lobe can therefore be displaced upwards with quite unusual facility. If the hyperextended position of the head is adopted it will be found that the frontal lobe actually falls away from the orbital plate, so that the route to the pituitary is opened up even without mechanical retraction, and all contusion of the brain is avoided.

There is no art in which the human factor is more important than in surgery, and it is therefore well that surgeons should have at their disposal a large variety of methods from which to choose. The stock of any instrument maker will show the efforts that have been made to meet their individual requirements, but I have sometimes wished that surgeons themselves would realize the essentially mechanical nature of some of the problems by which they are faced and the technical skill required to use successfully the elaborate appliances now placed at their disposal. It would be an immense advantage to the student if at some point of his training he were taught something of the mechanic's art, and realized the cunning of the hand involved in the dexterous use of even the simplest tool; for whatever the ingenuity of the instruments provided for the surgeon's use their success must ultimately depend on the skill of the hand which uses them.

THE SPA TREATMENT OF DISEASE.*

BY

RUPERT WATERHOUSE, M.D., M.R.C.P.,

PHYSICIAN TO THE ROYAL UNITED AND ROYAL MINERAL WATER HOSPITALS, BATH.

ALTHOUGH it cannot be claimed that there is anything strikingly new or original in the remarks that follow, it should in extenuation be borne in mind that systematic study of this branch of medicine has hitherto, I believe, found no place even in British universities so enlightened as that which this Branch is fortunate enough to possess within its area, and a presentation of some of the problems involved may not be without interest.

The virtues of the chalybeate waters of Spa, near Liège in Belgium, were known as early as the fourteenth century, and so famous was this resort some 300 years later that the word "spa" or "spaw" was adopted in this country as the generic term for any spring or well possessing medicinal properties, and later became extended to comprise any town or locality in the neighbourhood of such a spring.

The use of natural waters in the treatment of disease is, however, much older than this, and has obtained from remote times in most widely separated parts of the world—for instance, amongst the Greeks, Romans, Mexicans, Japanese, and Russians, to mention only a few. Even the Father of Medicine himself, Hippocrates, admittedly the greatest exponent of the healing art of all time, has every right to be regarded as a spa physician, since the site of the temple at Cos, where he practised, was, like that of the other Asclepia, selected for its climatic and other natural advantages, and great use was made of hydrotherapeutic and other physical methods of treatment—combined, however, it must be confessed, with a good deal of ritual and mystification. At one time there were as many as sixty or seventy of these temples of health or Asclepia in Greece, and many of them, being situated in the neighbourhood of healing springs, may be said to have combined the functions of present-day hospitals and spas.

In the early days of the revival of spa treatment haphazard drinking of, and bathing in, the waters were resorted to, but with their later development, as the result of experience and the scientific study of hydrology, their internal administration and external application became to some extent systematized, though modifications were, and always will be, necessary to meet individual needs. Many valuable adjuncts in the form of douches, massage, electrical treatments, physiotherapy, and so on have been added.

It is estimated that every year over one million persons seek relief at the European spas alone, and the fact that spa treatment has held its own for so long and is increasing rather than waning in popularity—notwithstanding the fierce competition of the latest synthetic drugs, animal extracts, vaccines, serums, psychotherapy, and the great development of surgery—leads to the natural query, What are the factors to which its success is to be ascribed? The answer, even by those who firmly believe that certain classes of patient will obtain benefit from spa treatment which they will obtain so rapidly and completely in no other way, is by no means easy.

These factors may be considered under three heads. The first may be termed the hydrotherapeutic—namely, the benefit to be gained from the administration of water internally and its application externally, considered as water simply and without regard to any other constituents. Secondly, the pharmacological factor—that is to say, the effect of the salts, gases, colloids, radium emanations, etc., which may be present in the water concerned, its electrical conductivity, and osmotic function. And thirdly, the general hygienic and psychical factors.

Internal Administration of Waters.

It is possible that much of the benefit of spa treatment is due to drinking large quantities of water. Many natural waters are isotonic, or nearly so, and can be taken in

* Presidential address to the Bath and Bristol Branch of the British Medical Association.

considerable amounts without damage to the gastric mucous membrane. This is not true of distilled water or other water of extreme purity, such as glacier water or that of the so-called "poison spring" at Gastein, which are known to have a definitely deleterious effect on digestion. Many natural waters, too, are thermal, and in certain cases it may be an advantage to avoid the abstraction of heat occasioned by the ingestion of much cold fluid. It was found, for instance, by Winternitz that the drinking of 500 c.cm. of water of a temperature of 46.5° F. caused a fall in the rectal temperature of nearly two degrees in twenty minutes.

Both reason and experience dictate that the ingestion of large quantities of water, such as is the practice at many spas, should take place when the stomach is empty. Otherwise, not only may digestion be retarded by dilution of the gastric juice and distension of the stomach, but absorption and excretion proceed less rapidly; and since, according to prevailing views, the object to be attained is a flushing effect on the tissues, this would be an obvious disadvantage. It has been shown that water taken when the alimentary tract is relatively empty reaches the duodenum in thirty seconds and the colon in five or six minutes, so that it is very rapidly absorbed and excreted, and conceivably helps in the elimination of bacterial toxins or poisons formed as the result of faulty metabolism.

Copious water-drinking leads to an augmented excretion of fluid—to some extent from the bowel, to a greater extent from the skin, but more still, at ordinary temperatures, from the kidneys. Not only is a greater amount of water passed, but there is said to be also increased excretion of urea, chlorides, sulphates, and phosphates. With regard to chlorides the increase is but temporary and is followed by a diminution, so that the total quantity of chlorides voided remains the same. The increase of urea, of phosphates, and of sulphates, however, is persistent—that is to say, continues as long as the additional fluid is imbibed—and, since no loss of body weight occurs, the probability is that not only is there a greater disintegration of the tissue elements which give rise to these, but that there is, in addition, an increased formation—in other words, a definite quickening of metabolism. This is confirmed by the recent experiments of J. B. Orr,[1] which show that excessive ingestion of water in healthy individuals leads to increased excretion of urinary nitrogen, increase of total nitrogen excreted as urea, marked increase in excretion of ammonia, and decrease in faecal nitrogen—results which he considers as evidence that both the anabolic and katabolic phases of protein metabolism are accelerated.

It was shown as long ago as 1910 that increased water ingestion diminished the number of bacteria in the faeces, and since one source of the pressor substances responsible for hyperpiesis appears undoubtedly to be bacterial action upon the proteins in the intestine, it is interesting to note that Orr[2] has found a definite fall of the systolic and diastolic pressures in both normal and hypertensive individuals after drinking three or four litres of water, though where diuresis is unable to keep pace with the intake the fall may be preceded by a rise above the original level. Increase in the parotid and pancreatic secretions has been observed in animals after copious water-drinking; the bile, too, is said to be increased both as regards its fluid and solid constituents, and its specific gravity diminished.

External Application of Waters.

With regard to the external application of water there is no need, after the admirable cinematograph demonstration given to the society as recently as last year by Dr. R. G. Gordon, even to enumerate the various methods employed, but some of the physiological alterations produced in the body may perhaps be considered—that is, as far as they are known, for although many careful and exhaustive experiments have been carried out there still remains much to be learned.

It has been calculated that the pressure in an ordinary bath of plain water is as much as 500 kilograms. The tendency of this pressure—a tendency which, however, may be counteracted by other factors—is to constrict the superficial blood vessels and thus to drive the blood into internal parts. This is probably the explanation of the diuresis which may result even from hot bathing. The chief effects of baths, however, probably depend upon the temperature at which they are administered. Baths at or about the temperature of the skin—namely, 93° F.—are designated athermal or indifferent. They have no thermal results, but have a markedly sedative action on the nerve endings in the skin, and through them on the nervous system as a whole, and are thus of value in relieving pain and facilitating movement in conditions where muscular spasm is present, as in some cases of chronic arthritis and the results of injury.

The subjects of paralysis from organic disease of the nervous system at one time formed a considerable proportion of those sent to spas, and R. G. Gordon[3] has of recent years given an impetus to the revival of this practice by stressing the value of the sedative influence of warm baths in relaxing muscle rigidity and the counteraction of the effect of gravity by the water in rendering passive and re-educative movements more readily performed. Baths of a higher temperature have additional effects. In the first place, the amount of perspiration is increased, and as much as a pound of weight may be lost in sweat by immersion in a bath for thirty minutes at a temperature of 100° F., or for a less period at a higher temperature; whilst Raiment's researches at the Royal Mineral Water Hospital show that its composition may undergo modifications the significance of which we are not yet in a position to appreciate. At the same time the body temperature rises. This is only to be expected, since loss of heat from the skin, whereby some 90 per cent. of heat loss normally takes place, is, with the exception of the small area of the face and scalp, entirely prevented. It is difficult to imagine in these circumstances, with the body immersed in a medium hotter than itself so that loss of heat by conduction, by radiation, and by evaporation is almost completely in abeyance, how the temperature can fail to rise if the production of heat is maintained at the former level. Indeed, it seems wonderful that it does not rise to a greater extent than is actually the case, for observations show that the intake of oxygen and the output of carbon dioxide may be increased by as much as 50 to 100 per cent., indicating apparently that metabolism is not diminished and slowed down, as might be anticipated, but actually increased. These facts are very difficult to reconcile, since the body temperature seldom rises as high as that of the bath, though Dr. J. B. Burt[4] found a slight rise of temperature in patients bathing in simple water at a temperature below blood heat—namely, about 96° F.

Recent experiments at the Department of Physiology at Pennsylvania showed that immersion in baths at 36° C., rapidly raised at the end of an hour to 40.2° to 43° C., caused a rise in body temperature at the rate of from 1.9° to 5.3° C. per hour, greater depth and rapidity of breathing, with marked diminution of the alveolar carbon dioxide tension, increase of the *p*H value of the plasma, and diminution of carbon dioxide in the blood. The urine was increased in quantity and became alkaline, in half the cases becoming even more alkaline than the blood.

These observations seem to show that the effect of hot bathing on metabolism is much more complex than was formerly supposed, and other detailed investigations into this interesting problem might profitably be undertaken. It is easy to understand, for instance, how an air temperature of 70° F. feels comfortably warm, whilst a bath at the same temperature feels cold, since water is a much better conductor of heat than is air; but it is difficult to explain the difference in one's sensations in water and in air at temperatures ranging from 100° to 105° F. The artificial pyrexia may persist for an hour or more after the bath, and is in all probability an important factor, especially in many so-called rheumatic conditions where the body temperature tends to be subnormal.

Of equal importance with the temperature is the length of stay in the bath. A hot bath of brief duration acts as a stimulant, but a bath too prolonged is succeeded by a condition of lassitude and debility, and even of tetany—results carefully to be avoided in practice. In this country the best results, where thermal effects are desired, have usually been obtained from baths at a temperature of 99° to 105° F., with a duration of fifteen to twenty minutes.

At Kusatsu in Japan the temperature of the water is 130° F.; the bather has to be encouraged to enter the water by the beating of gongs, and can only remain there two or three minutes. As a contrast to this, at Kawanaka, also in Japan, where the temperature of the water is just below blood heat, the patient stays in the bath for weeks on end, with stones in his lap to prevent him floating during sleep.

It has been stated that one result of hot bathing is to augment the amount of urea excreted; but the evidence on this point is conflicting, and though, as has been explained, it is difficult to conceive that metabolic processes can be increased whilst the person is actually in the bath, and while they, with the exception of the lungs and respiratory muscles, are perhaps rested, it may be that they are speeded up subsequently, especially if, as is frequently the custom, the patient is packed in hot blankets afterwards.

Schamberg and Rule[5] have demonstrated that syphilitic infection of rabbits after testicular implantation of the virus can be prevented by eleven daily baths, each for fifteen minutes, at 113° F., with an average rise of body temperature of 5° F., if the first bath be given within three or four days of inoculation; and that the disease in the chancre stage can be completely cured by fifteen such baths. Schamberg and Tseng showed that an emulsion of *Spirochaeta pallida* heated for one hour at a temperature of 40° C. failed to produce syphilis, though the spirochaetes were still motile. In treating by hot baths human beings suffering from syphilis they found perceptible improvement in the cutaneous manifestations, sometimes to the point of disappearance, but only a slight change in the Wassermann reaction. It must be borne in mind, however, that the normal temperature of rabbits is some four or five degrees Fahrenheit higher than that of man, and while the temperature of the rabbits was in some cases raised as high as 109° F., the highest point reached in human beings was several degrees lower.

These experiments suggest the possibility that the rise in temperature produced by hot bathing may have either a direct devitalizing action on the micro-organisms responsible for some forms of infection, or else may have an effect in raising the body resistance. Colebrook, Eidinow, and Hill,[6] in an inquiry into the effect of radiant and other heat on the bactericidal power of the blood, came to the conclusion that heat and other "insults" to the skin provoke or increase the defensive power of the body (*a*) by a direct effect in improving immunity, and (*b*) by stimulating the immunizing mechanism through the absorption of the products of tissue damage. Schamberg and Tseng also found, consequent on the hot baths given to syphilitic subjects, (*a*) a transient leucocytosis, followed by a brief reduction in the white cells; (*b*) a slight rise in systolic blood pressure and frequently a great drop in the diastolic pressure, both of temporary duration; (*c*) a fall in the blood cholesterol averaging 10 per cent.; (*d*) a rise in the blood sugar averaging 10 per cent.; and (*e*) no material influence upon the urea, nitrogen, blood uric acid, or proteolytic or lipolytic enzymes. Both hot and cold stimuli of a gentle nature are said to assist the circulation by stimulating the unstriped muscle fibres of the blood vessels, causing an alternate contraction and relaxation, the so-called peripheral heart of Onimus.

It is also claimed that bathing has an important effect on the "perspiratio insensibilis," which may include fluid not only from the sweat glands, but also water from the body tissues and the blood stream itself, whereby waste products, probably mainly acid, which the lungs are unable to deal with, are eliminated in the form of gases or vapours. Baruch showed, in a number of experiments on both healthy and diseased persons, that the number of red blood cells and leucocytes was almost constantly increased after hot bathing, and that there was a less marked increase of haemoglobin. A considerable increase of the relative quantity of acid phosphate in the blood, sometimes to as great an extent as 100 per cent., has also been demonstrated. The action of vapour baths, which, however, are given at a higher temperature—100° to 115° F.—resembles that of hot immersion baths as regards the production of pyrexia; but with hot-air baths, there being no hindrance to evaporation from the skin, there is little or no rise of body heat, whilst the amount of perspiration is even greater.

The effect of douches varies with the temperature at which they are given and the pressure employed. At extremes of temperature they are powerful stimulants, both locally, to the circulation at the spot where applied, and generally, by their reflex action on the nervous system. Subthermal douches at a low pressure are, on the other hand, pronounced sedatives.

The action of cold baths need not be exhaustively considered, since their chief therapeutic indications are in acute diseases rather than in the chronic maladies dealt with at spas. They cause an enormous increase of heat production, a slowing and strengthening of the circulation, and rise of blood pressure, and are, or should be, followed by a reaction in which the skin flushes and the mental and bodily vigour is increased. Cold, either as a brief immersion bath or as a douche, has therefore a valuable stimulant effect where this power of reaction is present, but must be used with caution in the debilitated and at the extremes of life, where this power is apt to be lacking. Of great importance, however, is the improvement which can be wrought by these means in the power of reaction of the skin. The Russian is said to go straight from his vapour bath to roll in the snow, and though it is not usual in this country to aim at a contrast quite so violent as this, there is no doubt that the nutrition and readiness of response of this organ, so essential in a changeable climate, can be vastly bettered by suitably adjusted hydrotherapeutic measures.

Pharmacological Effects.

When we come to discuss the pharmacological effects of natural mineral waters we find ourselves on even more debatable ground. Though he does not appear to be referring exclusively to waters of this kind, Hippocrates, over two thousand years ago, said that "as waters differ in their taste and weight so do they differ in their action upon the body."

Spa waters may be divided into the following groups: (1) the indifferent thermal, (2) alkaline, (3) acidulated, (4) calcareous, (5) sulphur, (6) muriated, (7) sulphated, (8) chalybeate, and (9) arsenical. Whilst many of these waters may produce the pharmacological effects to be expected from their chemical constituents it is not proposed to spend time on these, but to consider whether there may be, in addition, any specific factor or factors common, perhaps, to all, for it cannot be denied that waters differing widely in their characters often appear to be beneficial in the same classes of disorders.

The, at first sight, astounding theory has been advanced by some geologists that many thermal waters, and perhaps other natural mineral waters, are not derived, like the water of ordinary springs, by percolation from the earth's surface, but are formed primitively in the bowels of the earth by the union of nascent hydrogen and oxygen liberated in the breaking up by heat of granite rocks. Be this as it may, it appears to be established beyond question that it is impossible to reproduce by artificial means the conditions which are found in a natural mineral water, and there are various properties to which the therapeutic value of spa waters has been attributed, such as radio-activity, the presence of elements in the form of free ions, the colloidal condition of the substances present, and the presence of rare metals in minute quantity; whilst some hold that it is not so much in the variety of the elements and in their respective quantities, as in the relative proportions of those elements, that the property of a mineral water resides.

Although the water of ordinary springs, and even tap water, may contain traces of radio-activity, the amount is usually very much greater in the waters of spas, and some hold that this is an important therapeutic factor, especially since benefit has been claimed in diseases such as are usually alleviated at spas by the administration of artificially prepared radio-active water, which, too, has been shown to produce diuresis and increase the excretion of uric acid, carbon dioxide, etc., and to lower the blood pressure.

If radio-activity is indeed a factor of importance it affords a reasonable explanation of the time-honoured dictum that a spa water must be drunk at its source and not taken away in a bottle, for radium emanation is rapidly disintegrated, its period of decay, according to Ramsay, being four days. It must not be forgotten, however, that the quantity of radium or its products varies enormously in the different mineral waters, and that spas having little, claim—probably with justice—as good results for the same class of disorders as those having much, and it has recently been suggested that the secret may lie in the ionized or in the colloidal state of substances contained

in the water, or in the interrelationship between radio-active substance, ions, and colloids.

Noteworthy in this connexion are some experiments by Sarmento and Kopazcewski[7] with the water of Vidago, an alkaline water somewhat similar to that of Vichy, which, however, on standing becomes first opalescent, then yellowish, and finally clear again as the suspended particles settle. These investigators injected thirty-six guinea-pigs each with 0.4 c.cm. of 5 per cent. rabbit serum. Six were kept as controls; of the remainder, fifteen were injected daily with 3 c.cm. of fresh Vidago water, and fifteen with water which had been kept four or more days. At the end of twenty days all the guinea-pigs received an injection of 0.2 c.cm. of horse serum. The six controls died of anaphylactic shock. The animals injected with "dead" water showed distress, some becoming comatose, but all recovered within a few minutes. Those injected with fresh water showed no symptoms whatever.

Ferreyrolles[8] has shown that guinea-pigs and rabbits injected intraperitoneally or intravenously with Choussy Perriere water exhibited an increase of leucocytes in the blood to, roughly, double their previous number. A similar injection fifteen days later produced no leucocytosis, while a dose of typhoid toxin, lethal for animals of similar size, produced no effect.

Billard[9] injected three guinea-pigs with a dose of tetanus toxin—lethal in ninety-two hours—two days, seven days, and ten days respectively after injecting them with Choussy Perriere water. The first showed local tetanus of the abdominal wall but eventually recovered, the two others showed no symptoms. Billard has further demonstrated that certain neurotoxins—such as sparteine, snake venom, diphtheria toxin, and tetanus toxin—when mixed with various mineral waters may be inactivated so that doses ordinarily lethal produce no effect, different mineral waters inactivating different toxins.

Results such as these, of which only a few examples have been quoted of numerous similar experiments carried out on the Continent, suggest that there is still much to be learned if full use is to be made of these natural agencies.

Sneider, Bricaud, and Grigaut, in an examination of the blood of gouty patients undergoing treatment at Contrexéville, found that uric acid, excessive at the start, instead of diminishing, actually increased during the course of treatment, but was found to be much less a month or two later, the explanation suggested being that excess of uric acid in the tissues was being "washed out" into the blood, and only gradually eliminated by the kidneys. These findings have been confirmed at Buxton, the average increase of blood uric acid at the end of a three weeks' course being 1.9 per cent., while at the end of a further three weeks a reduction equal to 25.5 per cent. had taken place.

Another property of spa waters which has of recent years been the subject of investigation is their power of activating ferments. It has been shown, for instance, that trypsin added to various of the French natural mineral waters has from two to five times the digestive power of an equal amount in distilled or tap water, and no description of a French mineral water is now considered complete without mention of its "zymosthenic index." Examination of spa water by modern methods, and especially by the use of the quartz spectrograph, has in many cases revealed the presence of a much greater number of metals than older analyses showed, and when we learn that so infinitesimal a quantity of manganese as 1 part in 40,000,000 parts of water will determine the fruiting or not of certain plants, and that broad beans will perish unless they get boron, though so little as 1 part in 12,500,000 is sufficient, we may well hesitate to conclude that traces of rare metals such as caesium or rubidium are altogether without therapeutic effect.

J. B. Burt claims that there are three phenomena characteristic of the action of natural thermal baths which are not found after the use of simple baths: (1) that diseases are alleviated, the action on true gout being so decided that it might almost be called specific; (2) the occurrence of thermal crises, usually in the second week of treatment, characterized by increase of pains, lassitude, and mental depression; and (3) the supervention after treatment by too many baths or baths of too long duration of the condition known as thermal debility. None of these, he states, follow the use of baths of ordinary water. In a patient with a biliary fistula, Mayo Robson found that an aerated alkaline water increased the flow of bile more than any of the reputed cholagogues; other experimenters, however, have failed to confirm this.

Conclusions arrived at as the result of investigations into the effect of spa waters on the output of urine are somewhat at variance. Race[10] found that Buxton water given to gouty subjects has a definite and specific diuretic effect over and above that of distilled water: that it increases the elimination of sodium chloride; and that it decreases the hydrogen-ion concentration and favourably influences nitrogen metabolism by increasing the percentage excreted as urea and reducing the percentage excreted as uric acid and undetermined nitrogen.

It is important, of course, to remember, both as regards diuresis and diaphoresis in the maladies treated at spas, that it is not as a rule simply the elimination of water that is aimed at, but the removal by these means of deleterious substances or the products of increased tissue change.

Peskett and Raiment,[11] in a careful and laborious investigation, found that in healthy subjects Bath mineral water had no effect, as compared with tap water, in increasing either the volume of urine or the amount of total nitrogen, urea, or uric acid contained in it, but that there was some increased excretion of acid radicles and of phosphates. The value of their experiments, however, is very largely, if not entirely, discounted by the fact that the mineral water was given with meals, and not, as has always been the spa custom, on an empty stomach. Although its mineralization is so low as to bring it into the class of "indifferent" waters, the total solids only amounting to about 230 parts per 100,000, the Bath water when fresh presents under the ultramicroscope a perfect colloidal picture, and if the most recent views with regard to the importance of the degree of colloidal dispersion are correct, and when it is realized how readily the colloidal condition is destroyed by, for instance, an acid, it may well be that the time-honoured practice of insisting on these waters being taken before meals may be of paramount importance, and no experiments can be regarded as in any way conclusive unless carried out under these conditions.

General Factors in Spa Treatment.

Finally, there remains to be considered the influence of the various subsidiary factors which come under the heading of general hygienic and psychical. Every practitioner is alive to the profound effect which may be produced by transference from a bleak, dry, wind-swept area to a soft sheltered one, or, conversely, from a still, enervating climate to one fresh and bracing. Other differences of environment are of almost equal importance. Of still greater value is the enforced rest from the strain and anxieties of business, the worries of domestic details, or the enervating effects of dissipation. Change of diet, too, plays a part in assisting the change in metabolism which spa treatment is directed to bring about, while the drinking of large quantities of water, besides the physiological effects which have been mentioned, may mean the drinking of less whisky or less tea—no mean advantage in some instances. Then comes the question as to what part suggestion plays. The very use of the word "cure" for a course of treatment—considered by some a master stroke on the part of whoever originated it—at the outset tends to put a patient in the right frame of mind for responding to the influences that are brought to bear on him, and the effect is doubtless enhanced by the optimism of bath attendants, masseurs, etc., and by mingling with others who are receiving or have received benefit. Another factor of importance is the special experience that masseurs and masseuses obtain in regard to the particular class of patient that frequents the spa. Further, physicians at spas amass an experience of certain diseases much greater than falls to the lot of the general practitioner, and naturally tend to take a keener interest in them, especially since, being as a rule diseases of a chronic nature and not endangering life, they are likely to appeal less strongly to the family doctor than more dramatic happenings.

The foregoing observations, imperfect though they be, may incline you to believe that the potentialities of balneology are not inconsiderable. It will be evident, however, that treatment to be effective must be varied to meet different conditions and to suit different constitutions, and that any attempt to stereotype methods in the many diverse departures from health amendable to spa treatment is foredoomed to failure.

If there be, as many think, some specific influence in these natural waters, it must ever be remembered that it is not to be supposed that diseases will be cured by any direct action of such a remedy, but rather that it will,

like any other remedy, act as a stimulus to those defensive powers in the human body which need to be called into play, and that different individuals cannot all be expected to respond to the same stimulus to the same extent or even in the same manner. Analogies with the treatment of syphilis are suggestive in this connexion: it is well recognized that over-treatment of this malady may be as bad as, or perhaps worse than, no treatment at all, and that the problem in the cure of syphilis is not to get as much of the specific remedy into the body as possible, but that amount which is capable of producing the optimum response by the tissue defences in the individual concerned. Such a view of the mode of the specific action, if any, of a mineral water would go far to explain certain difficulties and anomalies which are sometimes encountered.

There is no doubt that there is a vast field for experimental research into the many problems connected with spa treatment, of which only the borders have as yet been explored. Further, there is need for more publication of the results of treatment of series of cases. It is to be regretted that physicians at spas so seldom put on record their experiences. For this there are probably three reasons: first, a natural, but perhaps undue, apprehension that such a proceeding lays the writer open to the charge of advertisement; secondly, the difficulty of following up the after-histories of patients who are only under direct observation for a short time; and, thirdly, the fact that many of the cases met with are of a very chronic character, and that so much damage has been already done that several courses of treatment may be necessary before the complaint is brought to a standstill, and even then full functional restoration may be impossible. I think it was Sydenham who said, "Chronic diseases require chronic treatment," and this is as true of spa therapy as of any other—a point perhaps not sufficiently recognized and insisted upon.

FRACTURES OF THE LOWER END OF THE RADIUS IN ADULTS

(*COLLES'S FRACTURE AND BACKFIRE FRACTURE*).

BY

HAROLD EDWARDS, M.S., F.R.C.S.,

JUNIOR SURGEON AND SURGICAL TUTOR, KING'S COLLEGE HOSPITAL;

AND

E. BELLIS CLAYTON, M.B., CH.B.,

DIRECTOR OF THE PHYSIO-THERAPEUTIC DEPARTMENT, KING'S COLLEGE HOSPITAL.

THE following account is based on an analysis of 424 cases of fracture of the lower end of the radius treated in the fracture clinic of King's College Hospital during the three years 1924–26. Of these fractures 251 occurred in women and 173 in men and youths. Of the latter number, no fewer than 84 were caused by backfire injury from cranking a car. The remainder, and all those occurring in women, with one exception—a backfire fracture—were of the Colles type. Cases of separation of the lower epiphysis of the radius, except those occurring from backfire injury, have not been included within the scope of this article.

THE COLLES TYPE OF FRACTURE.

In all there were 339 cases which might be regarded as of the Colles type, and sustained by falling on the outstretched hand: 250 were in women, and 89 in men. Radiograms, both antero-posterior and lateral, were available for examination in 275 of these cases.

(*a*) *The Radial Fracture.*

In the majority of cases the fracture was transverse, and at the upper limit of the radial surface which enters into the formation of the inferior radio-ulnar joint (Fig. 1). In a few cases the fracture was at a higher level (Fig. 2), and in others a shade lower (Fig. 3). In one case the line

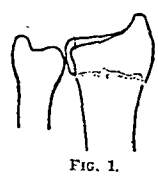

FIG. 1.

FIG. 2.

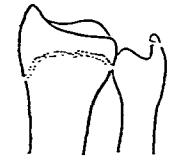

FIG. 3.

of fracture ran obliquely downwards from a point fully 1¼ inches above the radial styloid process (Fig 4). In cases where severe comminution was present the radiating line of fracture ran vertically up the shaft, and in some cases down to the joint surface. In a number of cases there was a single vertical split passing from the transverse fracture to the joint surface. *Radial rotation of the* lower fragment was present in all cases, but varied very much in degree in different fractures.

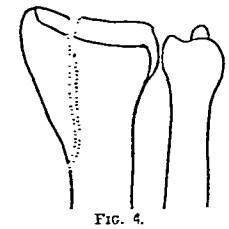

FIG. 4.

Lateral views showed a varied picture. In some there was no sign of fracture in the lateral plane. In a fair proportion of the cases the posterior lip of the radial articular surface was broken off. In a few cases there was little or no appreciable displacement, but in the vast majority there was backward tilt of the lower fragment, so that the articular surface of the radius faced downwards and backwards. This was usually, but not invariably, associated with bodily backward displacement of the lower fragment. In cases where the posterior lip of the radial articular surface was fractured the backward tilt was very marked. In a few cases the carpus was carried bodily backwards with the fractured posterior lip, so that the condition was actually a fracture-subluxation. It is important to remember that this is likely to be present when the deformity is gross, so that steps may be taken to ensure complete reduction. The articular surface appeared to be involved, usually in the manner described above, in 95 of the cases. It is not always possible to be certain of this point from the radiograms, but the figure indicates that the wrist-joint is involved in a high percentage of the cases.

It is doubtful how often the inferior radio-ulnar joint was involved, it being extremely difficult to determine this point. In some cases the joint was very obviously involved, but in the majority the fracture appeared to be just above the upper limit of that joint. It is a common experience to find pronation and supination the last movements to return fully after fracture, and although no correlation between delay in obtaining these movements and fracture into this joint has been found possible in this series, it appears very probable that joint involvement is the cause of the delay in most instances.

(*b*) *The Ulnar Fracture.*

In 153 of the 339 cases the ulna was fractured. In all but 8 of these the fracture was of the styloid process. In one case it was through the shaft fully three-quarters of an inch from the lower end. Fracture of the styloid process occurred in all situations, from the base to the tip. In one case two fragments were broken off.

Whether the ulnar styloid does or does not fracture depends to a great extent upon the amount of radial abduction into which the hand is forced at the time of impact. It would also appear to depend upon the anatomy of the styloid process itself. This varies very considerably. In some cases it is long and narrow, with a curve to the radial

side (Fig. 3). This type invariably fractures. In others the ulna ends in a rounded extremity, with little or no suggestion of a styloid process at all. All degrees are met with between these two extremes. In some cases the process is conical, with a pointed distal extremity and an extremely wide base (Fig. 8). This type rarely fractures.

Fracture of the ulna appears to make very little difference to the end-result. In fact, we have had frequent occasion to note that patients in whom the ulnar styloid is not fractured are more likely to complain of tenderness over the internal lateral ligament than those in whom fracture of this bone has occurred.

(c) *Other Fractures.*

In only one case was the scaphoid fractured in addition to the radius or ulna.

DIAGNOSIS.

There is little need to discuss diagnosis, which is usually a simple matter. Antero-posterior and lateral radiograms should always be taken, even when the diagnosis of fracture on physical signs is certain. Radiograms should be taken in all cases of wrist injury, for a linear impacted fracture may be present with no well-marked physical signs.

BACKFIRE FRACTURE.

There were 85 cases of backfire fracture, and the radiograms of all were available for examination. They comprised the following types in order of frequency.

1. Oblique fracture through the radial styloid process, with or without fracture of the ulnar styloid. The line of fracture was usually from the outer side to a point about midway along the articular surface, corresponding to the interval between the scaphoid and semilunar bones (Fig. 5). In some cases the line of fracture was longer and more oblique. In extreme cases it ran into the distal end of the inferior radio-ulnar joint (Fig. 6).

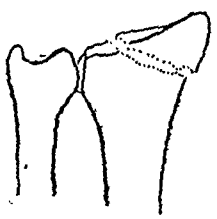

FIG. 5.

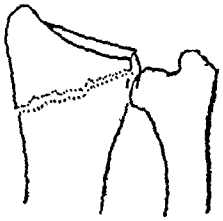

FIG. 6.

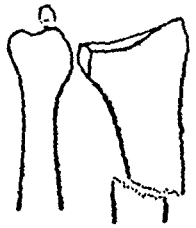

FIG. 7.

Displacement was not marked as a rule. The total number of cases was 28.

2. Colles's fracture (16 cases).

3. Injury to the epiphysis, in some cases with separation and backward displacement (12 cases).

4. High fracture (10 cases). The line of fracture was at or just below the junction of the lower and middle thirds of the radius, and was transverse or slightly oblique (Fig. 7). In two cases the ulnar styloid was also fractured. In this type the upper end of the distal fragment is carried just in front of the lower end of the proximal fragment, and the carpus and lower end of the radius are carried backwards.

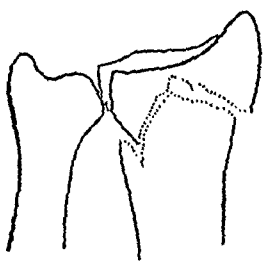

FIG. 8.

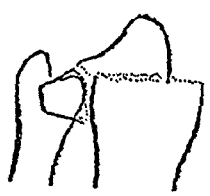

FIG. 9.

5. V-shaped fracture (7 cases). The styloid process was broken off, as in the oblique type, and in addition a fragment of similar size from the ulnar aspect of the radius (Fig. 8). The lines of fracture met at the mid-point of the radial articular surface, corresponding to the interval between the scaphoid and semilunar bones. In one case there was gross displacement of the fragments to the inner side (Fig. 9).

6. "High Colles" (6 cases). Fracture occurred well above the usual site for a Colles (Fig. 10). In one case both bones were broken at the same level. In the other cases the epiphyses had not yet united. This is of interest in that it suggests that the fracture resulted from a direct blow from the starting handle of the car.*

7. Ulna only, just above the distal end (2 cases).

8. Colles's fracture with inward displacement (1 case).

9. Atypical Colles's fracture, a combination of types 1 and 2 (1 case).

10. Trapezium only (1 case).

11. Radial styloid and scaphoid (1 case).

TREATMENT.

The treatment adopted in this clinic as a routine when deformity is present is reduction of the fracture under gas anaesthesia as soon as the diagnosis is made. The method used is that advocated by Sir Robert Jones—that is, disimpaction of the distal fragment by direct backward force, followed by replacing the fragment by direct force forward. The actual way in which this manœuvre is carried out varies with the individual operator, but there is never any call for the use of the older metl[illegible] the hand in order to obtain the necessary [illegible] care is always taken to correct the backward tilt of the lower fragment, and the radial deviation. This is of far more importance than the correction of the backward displacement, though this also should receive attention. When reduction has been obtained the wrist is kept in flexion, and is held in this position until the splint is applied. As has been stated, the carpus may be bodily displaced backwards (fracture-subluxation). This displacement is easily corrected if the wrist is fully flexed. A lateral *x*-ray photograph is taken immediately after reduction and fixation on the splint, as a routine. If the backward tilt is uncorrected (except in certain instances—*vide infra*), a further attempt at reduction is made.

The results of treatment go to show that unless perfect reduction of the backward tilt is achieved a perfectly functioning wrist-joint is not obtained. In interpreting the radiogram after reduction it should be borne in mind that normally the radial articular surface faces slightly *forwards*. The only exceptions to the rule of obtaining perfect reduction of the backward tilt are:

(*a*) In old people, if this has not been effected at the first attempt. Each case is seen by the surgeon at the clinic, and in the aged, rather than submit them to the ordeal of a second anaesthetic, it is usually adjudged satisfactory if the tilt is corrected sufficiently to allow the radial articular surface to face directly downwards.

(*b*) When severe comminution is present. In such cases, although it may be possible to replace the lower fragments by manipulation, it is often impossible to retain them in position. The bone is so pulped that the splint fails to give the necessary support, and the deformity recurs.

It may well be asked why in this clinic we attach such importance to the correction of the backward tilt. In our experience an uncorrected tilt invariably results in a weak wrist. Reference to the diagram (Fig. 11) will show that when this tilt is uncorrected the flexor tendons cannot act

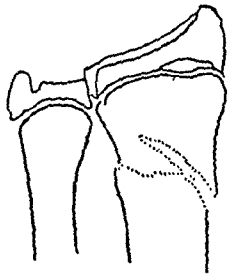

FIG. 10.

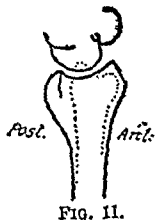

FIG. 11.

along their normal straight line, and this may impair their mechanical efficiency to some extent. The main cause of the weak wrist, as Mr. H. A. T. Fairbank permitted one of us to point out in the previous communication already referred to, lies in the fact that the radial articular

* For a more detailed account of the mechanism of backfire fracture see communication by one of us (H. E.) in the *Journal of Bone and Joint Surgery*, vol. 8, No. 4, pp. 701-717.

surface faces downwards and *backwards*. The pull of the long tendons passing over the back of the wrist-joint tends to make the carpus slip backwards over the obliquely disposed radial articular surface. For this reason the muscles act tentatively, and not to the full extent of their power, and the natural outcome is a weakened wrist. In late cases of unreduced backward tilt a successful result has attended operative reduction of the deformity by means of a curved osteotomy.

The chief significance of an uncorrected radial deviation lies in the remote rather than in the immediate result. The mechanism of the wrist is permanently upset, and though perfect function may be obtained for the patient before he finishes treatment, yet the joint is predisposed to the development of arthritis in succeeding years. Except for the unsightly deformity, an unreduced backward displacement is of little importance, and in no way interferes with the obtaining of a perfect functional result. It is the joint which matters, and be a fracture of the radial shaft anywhere along the course of the bone, near to the wrist-joint or remote from it, minor degrees of malalignment do not prejudice the issue.

Splinting.

The essential feature is to keep the wrist straight or slightly flexed to prevent the distal fragment from slipping back into deformity. In this clinic Carr's splint is used as a routine. Used in the correct way, Carr's splint is very efficient, and possesses many advantages over the various splints which have been invented to supplant it. It is very cheap and easily made, and when well applied is comfortable. It is important not to have the splint too wide. It should be a shade narrower than the diameter of the forearm just above the wrist. If wider the wrist will not lie snugly, and lateral movements will be possible. The splint does not hamper finger movements, which we regard as being of extreme importance in preventing stiffness and preserving the tone of the long flexor and extensor muscles. The patient is encouraged to perform them from the outset. Lastly, the splint is made of wood, and permits of *x*-ray examination after reduction. The splint is applied as follows:

The forearm, after reduction, is placed on the splint, which is covered with a very thin layer of wool. One pad of wool in addition is arranged under the lower end of the proximal fragment. The height of the pad can be varied to suit each individual case, and the extent of palmar flexion required thereby adjusted. A second pad is carefully placed over the distal fragment to maintain its position and prevent it from slipping back. With the arm held on the splint by an assistant fixation is obtained by means of two strips of adhesive plaster one inch wide. One, the first applied, passes over the pad on the distal fragment to secure the latter firmly in position, and a second is placed higher up the forearm to hold the splint in position. A calico bandage is bound over all, one turn passing between the thumb and first finger to prevent wrist movement, and after ascertaining that the circulation in the fingers is unimpaired, a lateral radiogram is taken: this should be examined before the patient leaves hospital. A poor result, particular attention being paid to the backward tilt, will necessitate a further attempt at reduction, unless this is contraindicated by age or the degree of comminution of the fracture. This second attempt should not be delayed for more than a few hours.

We do not adhere rigidly to Carr's splint, however, although it is used in the vast majority of the cases. If there has been very gross backward displacement and tilt, a posterior curved splint of aluminium is occasionally used, which permits of holding the wrist in full flexion. This splint has been found particularly useful in cases of fracture with complete separation of the radial epiphysis —one of the types of backfire fracture, and one often extremely difficult both to reduce and to hold in reduction.

Treatment of the various types of backfire fracture is carried out upon similar lines, with obvious exceptions. In the high type (No. 4) the arm is usually placed in supination on a back splint after reduction, followed by plaster in a few days. In one case in the present series it was found necessary to perform an open operation and plate the bone.

Massage and Movements.

Massage and movements are undertaken chiefly by students training as masseuses, who work under supervision. The interval elapsing between the injury and the time of commencement of massage varies. No hard and fast rules are followed with regard to the time of commencement, but, generally speaking, massage is commenced during the first week in old patients, and delayed for anything up to fourteen days in younger patients. The general routine carried out by the masseuse is as follows:

For the first fortnight after reduction massage is given on the splint, and the only movements permitted are finger movements. These, as stated previously, are very important. When there is much pain and swelling, or stiffness of the joints, or when the patient is nervous, these movements are assisted by the masseuse. Massage consists of effleurage to the fingers, back of hand, and forearm. This is given with the utmost gentleness, since undue pressure over the forearm might result in recurrence of the displacement of the distal fragment. We have found that pain over the internal lateral ligament of the wrist is a common complication. Friction massage is therefore given over the ligament after the seventh day, making this deeper after three weeks. For swelling and stiffness of the fingers friction massage is employed over the joints and dorsal tendons in addition to effleurage. Early in the treatment the shoulder movements are tested. When any limitation is found, the joint is taken through its range of movement at each attendance, and the patient instructed to perform this exercise at home.

After fourteen days the forearm is lifted off the splint on to a table. The anterior surface of the forearm is now massaged as well as the posterior, kneading massage being employed as well as effleurage. Flexion and extension and rotation movements are usually commenced at this stage. The wrist is gently flexed and extended over the edge of the table, either passively or assisted, the masseuse placing one hand over the lower end of the radius to support the fracture. It is important that the distal fragment be firmly supported to prevent movement occurring at the site of fracture instead of at the joint. Flexion and extension movements are followed by very gentle passive or assisted supination and pronation. The hand is held in ulnar deviation to avoid strain on the internal lateral ligament while these various movements are being performed. The splint is worn from three to four weeks, and followed by a sling for a few days, when active wrist, pronation and supination, and full finger movements are practised by the patient at home.

Duration of Treatment.

The average duration of treatment for all cases is nine and a half weeks. This figure takes into consideration a number of chronic patients who attended the physiotherapeutic department for upwards of nine months. If these be excluded it is found that the average duration is about six weeks. In the winter months it tends to be longer than in the summer months. This observation suggests that radiant heat may be of some value in the treatment.

We do not propose to enter into a discussion of the merits and demerits of immediate massage and movement as advocated in some clinics, this article being intended as a simple review of the treatment of cases as carried out at King's College Hospital Clinic. It would not be out of place, however, to point out the reasons why, at this clinic, the after-treatment of the fractures described above is followed.

In the first place, great emphasis is laid upon obtaining and maintaining a good reduction of the fracture. Experience shows that a good alignment affords the best prospect of obtaining a perfect wrist. It cannot be denied that good function often follows a poor reduction. Neither can it be denied that an occasional perfect reduction is attended by a relatively poor function. In the main, however, when a large series of cases are reviewed, there is no doubt that good reduction yields the higher percentage of good results. It must be borne in mind, also, that a malunited fracture, in respect of the radial deviation and the backward tilt, predisposes the wrist to the development of arthritis, and this may mar what had been regarded as a good result in the first year or so after the injury. Massage and movement in the first few days—especially movement—is attended by a very real risk of the distal

fragment being redisplaced. Doubtless the skilled surgeon can safely perform early passive movement, but in the busy rush of hospital practice, where this type of fracture is of such frequent occurrence, this is impracticable, and the work must be done in a department wherein students are being instructed. Apart from this there is a very cogent reason for the postponement of movement. The wrist-joint has been subjected to very severe trauma, and for the first few days it needs complete rest. Movement at the outset probably does more harm than good, and possibly favours the development of traumatic arthritis. The period of complete rest must not be too long, however, especially in old people, for fear of obtaining a stiff joint. A happy mean between too prolonged rest and too early movement is the ideal, and in this clinic we try to attain it. With regard to massage itself, we are convinced that it is not of great importance in the younger patient. Active finger movement does far more to preserve the tone of the long flexor and extensor muscles than massage can possibly do. In old patients the soothing effect of massage is of value, and, as stated, is usually employed during the first week.

It is difficult to give full credit to the very high percentage of good results claimed by some clinics for Colles's fracture. There are so many factors which tend to deprive the surgeon of a perfect result in every case. Not the least of these is the personal factor. We have had frequent occasion to note how two identical fractures undergoing identical treatment vary in the end-result. One patient may obtain a wrist sufficiently sound to admit of his discharge at the end of four or five weeks, while the other drags on for many months with stiffness of the joints, and perhaps pain over the internal lateral ligament. Another factor which is an absolute bar to obtaining uniformly good results is pre-existing arthritis of the wrist and fingers. Examination of this series of radiograms shows this to be of very frequent occurrence. It was present in 26 out of 360 cases (7.2 per cent.). The injury always makes the arthritis worse and the fingers more stiff, despite the fact that in such cases massage is employed at the outset.

The following table has been compiled from the notes of the cases, and gives some indication of the relation borne by the time of commencement of massage and movement to the result obtained. It will be seen that the percentage of good results remains fairly constant irrespective (within reasonable limits) of the time of commencing massage and movements.

	No. of Cases.	Average Duration of Treatment (days).	Percentage of Perfect Results.
Massage commenced—			
Under 10 days	92	67	70
Over 10 days	95	69	78
Wrist movement commenced—			
Under 14 days	65	68	75
Over 14 days	116	62	77
Splint discarded—			
Under 21 days	31	66	84
Over 21 days	155	67	73

These figures are not to be regarded as absolute, and are not intended to be final arguments for or against early massage and movement. They are merely mathematical calculations based upon the material available. For instance, the fact that of 31 cases in which the splint was discarded before three weeks the proportion of good results is 11 per cent. higher than those in which the splint remained on for a longer period in no way indicates that this is the optimum time for splint removal in every case. Of these 31 cases many were linear fractures without displacement, and probably would have done equally well had they not worn a splint at all.

LATE RESULTS.

When it comes to making a definite standard of results difficulties at once arise. It is impossible to set a standard of efficiency beyond which all results are declared good and the others poor. What would be considered a good result in an old arthritic patient might be deplored as a comparative failure in a young working man. Moreover, the following results are based upon answers to a questionary. One patient with a determination to be well will submit a satisfactory report. Another, determined to make the most of it, will discover some complaint even if he has every reason to be satisfied with the result obtained.

The number of copies of the questionary sent out was 416, and the replies totalled 321 (this includes the backfire fractures). In 235 of these (73.2 per cent.) there was no complaint of any kind, and no degree of incapacity to carry out the normal occupation. Many of these cases were in old people, who were obliged to do little or no work, and the fact that they admit being able to carry on with their normal occupation means nothing. For them, however, the result was satisfactory, and they are therefore included in the perfect results.

In the next category are placed all patients who put forward minor complaints, such as "feels stiff in cold or damp weather," "aches after use," "rheumatism in the fingers," "occasionally swells after use." The number of these cases is 74 (23.1 per cent. of the total). All are able to carry out their normal occupations. It is not easy to find causes for every one of these minor complaints: 23 of them had arthritis of the wrist or finger-joints, or both, before the injury; some of them, no doubt, have developed arthritis since. (The cases, it will be remembered, are those of from two to four years ago.) In some of the older patients reduction was not perfect, and they were left with a minor degree of backward tilt. Two of the patients developed small localized thickenings of the palmar fascia; one was a rheumatic subject, but the other was definitely not so; the thickenings were tender. It may be that they arose from irritation of the cross-piece of the splint, or from being bound too tightly in the splint after reduction.

A fairly common complaint is tenderness over the internal lateral ligament. This occurs early after fracture, and has been referred to previously. It appears to be more common in the female than in the male patients. The tenderness usually disappears after treatment, but in a few cases persists. In some of the cases there is some degree of limitation of both flexion and extension, and of rotation at the time of discharge, but this appears to clear up very quickly on the patient's return to work. Occasionally the limitation is very marked both in the wrists and fingers, and persists in spite of treatment. A few of these cases are functional, for the joints become quite mobile under anaesthesia without forcing. An anaesthetic usually cures all but the worst cases of this type. Limitation of movement in one plane only is invariably due to adhesions. Such cases are manipulated under gas anaesthesia. One manipulation is usually sufficient to cure the condition, but occasionally it has to be repeated, for the tendency to relapse is a very strong one. Limitation of rotation is more common than that of flexion and extension, and a certain number of these cases are manipulated. The delay in the return of full pronation and supination probably depends upon involvement of the inferior radio-ulnar joint in the fracture.

The type of work the patient has to do is a factor. Swelling and aching after use are more likely to occur if the occupation be a hard manual one than if it be, say, clerical. Some of the patients write to say that they have no discomfort with ordinary work, but notice pain or weakness after playing tennis. Such patients are mostly of the typist class. The majority of the female cases are occupied in housework, with its varied and manifold duties, some light, some heavy. It is after a day at the wash-tub that their wrists are most likely to make themselves felt.

Such complications as these enumerated are treated upon the following lines. Radiant heat, constant current

or diathermy, is used in addition to massage for pain over the wrist; when this is associated with stiffness, faradism to the forearm muscles is sometimes tried, also sinusoidal current arm baths. When stiffness of the joints persists after eight weeks without pain, the masseuse gives movement of the stiff joints with a steady pull on the resisting muscles. The patient also performs active mobility exercises—pronation and supination with a weighted stick, and wrist flexion and extension by means of a pulley, the patient assisting movement by pulling on the rope with the sound hand. To lengthen the lever arm, the hand is fixed in a clamp and the rope attached to a bar projecting from the distal end.

The remaining 12 cases (3.7 per cent. of the total) may be regarded as bad results. This group is at once the most interesting and instructive, as it gives some indication of loopholes in the treatment. The cases are given in detail.

Ref. No.	Sex.	Age.	Type.	Notes.
C15	F.	57	Colles	Open operation at another hospital. [illegible]
D45	F.	50	Colles	[illegible] ness of wrist and fingers.
A30	M.	61	Backfire, Type 1	Attended for 73 days. Pain and stiffness in wrist: no displacement. Commenced massage on sixth day and wrist movement on thirteenth.
C5	M.	40	Backfire, Type 2	Painful weak wrist, with marked limitation of movement. Marked osteo-arthritis before injury. (There was severe comminution in this case.)
D12	F.	53	Colles	*Painful weak wrist; grip poor; fingers stiff.* Marked osteo-arthritis before injury.
D3	F.	43	Colles	Painful stiff wrist; third and fourth fingers stiff. Very marked comminution with severe backward tilt before reduction. Massage commenced ninth day, and wrist movement on eleventh. Splint discarded on eighteenth day.
E2	F.	41	Colles	Marked limitation of rotation; wrist painful. Massage commenced on third day, wrist movement on sixteenth.
E26	F.	56	Colles	Always stiff and very painful after use. Osteo-arthritis present before injury. Massage commenced on third day, wrist *movement on sixteenth.*
F12	F.	42	Double Colles	*Right wrist:* Weak, with marked backward tilt. Operation by Mr. Fairbank, 1925. Now satisfactory. *Left wrist:* Perfect result.
J16	F.	52	Colles	Wrist and fingers very stiff. Attended for 18 months. Slight unreduced backward displacement.
K11	F.	52	Double Colles	*Right wrist:* Constant pain in wrist; swollen at night. Marked unreduced backward tilt. *Left wrist:* Perfect result. Slight backward displacement, but no tilt.
L9	M.	38	Backfire, Type 2	Backward tilt with a weak stiff wrist.

It will be noted that in three of the cases arthritis was present before injury, and was probably responsible for the bad result. One case (C15) came to the clinic after an open operation at another hospital. Another (D45) attended for a few days after injury, and was then not seen for a period of nine months.

An instructive case is that of F12. Both left and right wrists were fractured. In the left the position was good, and a perfect result was obtained. In the right there was marked backward tilt and a weak wrist in consequence. This was operated upon by Mr. Fairbank, the tilt being corrected by a curved osteotomy. Two years later the patient reports that the wrist is satisfactory, and gives no trouble with housework. K11 also had a double fracture. On the left there was a slight degree of backward displacement, but no tilt, and a perfect result was obtained. On the right there was backward displacement with tilt, and a bad result was obtained. L9 was also left with an unreduced backward tilt. These three cases well illustrate the importance of correction of the backward tilt. In the four remaining cases, no cause for the failures can be assigned.

We wish to thank Mr. H. A. T. Fairbank for the very kindly interest he has taken in this article, and both Mr. Fairbank and Mr. St. J. D. Buxton for allowing us to make free use of the material upon which it is based. Our thanks are also due to Dr. Grace Batten for looking up the very numerous radiograms.

MINERS' CRAMP.

BY

E. M. BROCKBANK, M.D., F.R.C.P.,

HONORARY CONSULTING PHYSICIAN, ROYAL INFIRMARY, MANCHESTER; MEDICAL REFEREE FOR INDUSTRIAL DISEASES.

A CASE of miners' cramp which has lately been under my care is, I think, of sufficient interest to record as the complaint is not uncommon, although references to it in literature are very scarce, and whilst it arises out of and during the course of employment and may make a man lose time for a couple of weeks or more, it is not a scheduled disease under the industrial section of the *Workmen's Compensation Acts.*

A miner, aged 44, was sent to me by his doctor for curious attacks of cramp, which came on while he was working. They began suddenly in the fingers and toes (in tetaniform manner), increasing in severity and gradually ascending the limbs to the back and neck. The cramp in the trunk and limbs lasted a few minutes, then eased somewhat in the limbs, but the hands and feet still remained more or less contracted and would continue so for three to four days. He would then feel well enough to return to work, although not in his former vigour. He has vomited with the severity of the pain. He has had about six or seven attacks during the last two years. He works in a mine, *which he says is very hot and dry, and perspires to a considerable* amount whilst working, and also when walking about after recovering from an attack of cramp.

During his working hours (one shift 5.30 a.m. to 2.30 p.m.) he drinks five to six pints of water, followed by about a pint of tea with his dinner, and half a pint for tea, and he takes about four glasses of beer in the evening—that is, about 8½ pints of fluid in the day. He does not take salt except with his food, and has no particular desire for salt food, as some miners who suffer from the cramps have. His other workmates have complained of similar troubles, but not to such a marked degree. He had been a miner since sixteen years of age, except for fourteen months in 1919-20, when he worked in a bleach-works. He is below the average stature and the robust physique of a miner. Two years ago a large piece of coal fell on his head, and he was laid up for seven to eight weeks, septic poisoning following in the wound. A few weeks after resuming work his face became swollen for nearly a week, and he was off work about three to four weeks with this illness. It was shortly after this that the cramp commenced.

There were no objective signs of any organic disease. The urinary chloride content was not investigated because I must confess to have not known what was the cause of the man's illness until I looked up the very scanty literature on the subject, and then it was too late for thorough clinical examination. The cerebro-spinal fluid was normal. There was no evidence to show that the injury had anything to do with causing the cramp, unless it had debilitated his system and made him more liable to it than he had previously been.

Descriptions of fireman's or stoker's cramp in medical literature are fairly common, but I have only been able to find two references to miners' cramp anywhere. One is of a somewhat popular but striking nature by J. B. S. Haldane.

"Perhaps the hottest place in England is about a mile underground in a well-known Lancashire coal-pit, where the miners work in boots and bathing drawers, and empty the sweat from their boots at lunch. One man sweated eighteen pounds in the course of a shift, and it is probable that even this figure has been exceeded. This sweat contained about an ounce of salt—twice what the average man consumes in all forms per day. The salt loss was instinctively made up above ground by means of bacon, kippers, salted beer, and the like. And as long as they did not drink more than a quart of water underground no harm came to the miners. But a man who has sweated nearly two gallons is thirsty, and coal-dust dries the throat, so this amount was often exceeded, and the excess occasionally led to appalling attacks of cramp, often in the stomach, but sometimes in the limbs or back. The victims had taken more water than was needed to adjust the salt concentration in their blood, and the diversion of blood from their kidneys to their muscles and skin was so great that they were unable to excrete the excess. The miners in question were offered a solution of salt in water, which was of about the composition of sweat, and would be somewhat unappetizing to the average man. They drank it by quarts and asked for more. And now that it has become their regular beverage underground there is no more cramp, and far less fatigue. It is almost certain that the cramp of stokers, and of iron and glass workers, which is known to be due to excessive water drinking, could be prevented in the same way."

The other paper is by K. Neville Moss, professor of coal-mining, Birmingham University, and is so important from a medical point of view that I take the liberty of quoting freely from it, and recommend all interested in the subject to read it in its complete form. Its title is "Some effects

of high air temperatures and muscular exertion upon colliers."

Miners' cramp has hitherto been observed only among the workers in hot mines where the temperature varies between 98° and 102° F. dry bulb, and 83° to 87° F. wet bulb, and, as far as Moss knows, only in Agecroft and Pendleton pits. Where cases of severe cramp do not occur miners may be partially disabled in respect of working capacity by the same cause that leads finally to attacks of cramp. This subject is of general importance, therefore, in connexion with deep mining problems of the future, and in connexion with other industries where men are performing hard work at high temperatures.

The number of cases severe enough to warrant the carrying of the men out of the pit was only nine in two years, but minor attacks of cramp occurred more frequently, and would no doubt have developed into severe cases had not the men ceased work immediately.

The cramp may be attributed to: (*a*) high air temperature, (*b*) excessive drinking of water due to (*a*), (*c*) continued hard work. Men are generally affected by it during the second half of the shift, and always in the muscles actually being strained at the time. Sufferers are generally men of poor physique. If a man is attacked whilst lifting a full tub on to the rails cramp might occur in the arms, legs, or abdomen. If the latter, the man is put out of action immediately, the contortion of the abdominal muscles being so great as to form a lump the size of a cricket ball.

In severe attacks of cramp it may take half a dozen men to hold down a sufferer and straighten out the affected limb. Such treatment produces excessive exhaustion of the sufferer, and sal volatile is usually administered to revive him. Professor J. S. Haldane suggested that cramp may depend on excessive loss of chlorides by continued sweating, and the matter was then investigated by Professor Moss, Mr. J. B. S. Haldane, and Professor A. V. Hill at a deep coal face at Pendleton Colliery. A sample of urine obtained at the end of the shift from one of the colliers who was subject to cramp gave not the slightest cloudiness with silver nitrate, though only 5 c.cm. were secreted during four and a half hours. This excessive shortage of chlorides in the urine must have been brought about by a combination of excessive sweating and drinking of water. Sweating by itself could have no such effect, as sweat contains only about 0.2 per cent. of chloride, and sweating by itself would tend to concentrate the chloride in the blood plasma.

Rowntree produced water poisoning in animals by injection of large quantities of water into the stomach through a tube. The animals showed the severest symptoms, including twitching of muscles, passing into convulsions.

Water poisoning, or miners' cramp, can be avoided by supplying the miners with a drink containing just sufficient salt to balance the loss of salt by sweating—that is, 6 grains of sodium chloride in a gallon of water. The results recorded by Professor Moss are most interesting and of importance, as will be seen from the account of one case in which the saline drink was given.

The man was of poor physique; he drank eight pints of water during the shift. He had been a frequent sufferer, but since taking salt each day for three months had had no sign of cramp. His evidence was as follows: Appetite much improved; feels quite fresh after a shift's work, where formerly he was obliged to cease work at about 12.30 p.m. each day owing to excessive fatigue; his life at home was changed from one of laziness and sleep to one full of energy; in general he feels a changed man.

My own patient was given a similar saline to drink and he has kept well at his work up to date.

PREGNANCY ASSOCIATED WITH DIABETES MELLITUS.

BY

K. SHIRLEY SMITH, M.B., B.S., B.Sc., M.R.C.P.,

MEDICAL REGISTRAR, THE MIDDLESEX HOSPITAL;

AND

FREDERICK ROQUES, M.D., M.CHIR., F.R.C.S.,

GYNAECOLOGICAL AND OBSTETRIC REGISTRAR, THE MIDDLESEX HOSPITAL.

PREGNANCY in a diabetic patient is commonly regarded as an extremely rare event. Not only is there a predisposition to sterility in diabetes, but it was, until recently, held that there is a strong probability of death or miscarriage should pregnancy occur. A. L. Walker[1] last year reported a case of pregnancy and labour in a diabetic woman, the first to be treated in the department of obstetrics at the Middlesex Hospital in a series of 10,000 confinements. Not a single case could be found in the records of the City of London Maternity Hospital among 27,567 patients confined. In reviewing the problem Walker argued that with the advent of insulin, and by the abolition by this agent of hyperglycaemia and acidosis, the risks attending pregnancy in a diabetic woman are not so great as in the days before the isolation of the internal secretion of the pancreas. It further seems to us that by the employment of insulin pregnancy in diabetic patients is rendered more likely.

The following case is of interest since it illustrates certain features of the association of diabetes with pregnancy, and it further throws some light upon the effect of insulin in this combination.

The patient, aged 34, was admitted to the Middlesex Hospital under the care of Dr. C. E. Lakin on June 14th, 1928, on account of diabetes associated with pregnancy.

There was nothing relevant in the family history except that one cousin had diabetes. There had been one previous pregnancy, in 1918, when a healthy child of 6½ lb. was delivered at term. In 1924 the patient began to lose weight, and sugar was discovered in the urine. She was then treated for diabetes in the Middlesex Hospital for four weeks, continuing to attend thereafter as an out-patient. In 1926 her condition deteriorated, and she [illegible] put on insulin treatment. Equilibrium was [illegible]tained by doses of 10 units twice daily on a [illegible]130 calories. In [illegible], she became pregnant; the date of the last menstrual period was not accurately known, but she thought it was at the end of October, 1927.

No new symptoms had been experienced since she became pregnant, and on admission the patient appeared to be in good health. The urine contained a trace of sugar; Rothera's and Gerhardt's tests were positive. The blood contained 202 mg. of sugar per 100 c.cm. This and subsequent routine estimations were conducted four hours after breakfast. The tests for albumin were negative. No physical signs were observed in the cardio-vascular system, in the respiratory system, or in the nervous system. She was then from 31 to 32 weeks pregnant. The vertex was below, the back in front and to the right. Foetal movements could be felt, and on June 30th the foetal heart was heard.

The patient was put on Allen's twelfth day diet (1,560 calories) and given 10 units of insulin daily. While under this treatment the blood sugar fluctuated between 200 and 220 mg. per 100 c.cm., but the excretion of sugar by the kidneys increased, the urine on the fifth day after admission containing 1 per cent., or 32 grams of sugar in twenty-four hours. The dosage of insulin was accordingly increased to 20 units twice daily, under which treatment the blood sugar gradually fell to a normal level, which was reached two weeks after admission. With this dosage of insulin and on Allen's tenth day diet (1,300 calories) the hyperglycaemia did not recur and the urine remained sugar-free but for occasional traces. Rothera's test, however, remained constantly positive, while Gerhardt's test was generally negative.

At 7.30 p.m. on August 15th, nine weeks after admission to the hospital, she went into labour and was transferred to the department of obstetrics under the care of Mr. Comyns Berkeley. Labour was normal; the presentation was a second vertex; the three stages of labour occupied respectively 2 hours, 15 minutes, and 15 minutes. The puerperium was apyretic and involution took place normally. The condition of the urine remained the same as before labour, a trace of lactose being present occasionally and Rothera's reaction remaining positive.

The child, a male, was healthy at birth and weighed 7 lb. 11½ oz., measuring 20 inches in length. It was fed at the breast from birth. During the first three days of life the weight fell to 7 lb. 4½ oz. On the eighth day after delivery the weight was the same as that recorded at birth. Thereafter a steady gain in weight was recorded. The content of sugar in the child's blood was normal and the urine showed no abnormality.

On August 16th, the day following delivery, the blood sugar of the mother was normal—100 mg. per 100 c.cm.; but by August 20th it fell to 45 mg. per 100 c.cm. A specimen of blood withdrawn before breakfast on August 21st contained only 41 mg. of sugar per 100 c.cm. of blood, while the patient complained of drowsiness and blurred vision. She became hot and cold alternately. An onset of hypoglycaemic coma being feared, she was at once given two teaspoonfuls of sugar with the juice of an orange. By 2 p.m. on the same day, as a result of this treatment, the blood sugar had risen to 165 mg. per 100 c.cm. and she had lost her feeling of drowsiness.

Thereafter the dose of insulin was reduced to 10 units twice daily in association with Allen's tenth day diet (1,300 calories). The blood sugar during the remainder of the patient's stay in hospital fluctuated between 65 and 90 mg. per 100 c.cm. She was discharged on September 6th, and seven weeks later was found to be sugar-free on the same diet and insulin dosage.

This case illustrates several important points and confirms Walker's conclusions. First, it shows that treatment with insulin renders sterility less probable in diabetic patients. Far-reaching conclusions cannot be drawn from a study confined to one case, but it appears to us at least possible that the patient would not have become pregnant before the days of insulin. Support is given to this conclusion by one of Bowen's cases.[2] Secondly, it suggests that the dangers associated with pregnancy and labour in diabetic women no longer exist. Thirdly, there can be no doubt that the requirements of a growing foetus put a strain upon the resources of a diabetic patient, as was taught by the older writers. This is shown by the fact that six days after delivery the blood sugar fell to an alarmingly low level. Only half as much insulin had to be given after the birth of the child as before. Parsons, Randal, and Wilder[3] recorded two cases of pregnancy in association with diabetes in which the dose of insulin required reduction after labour. In both their cases the larger dosage had to be resumed some time later. Fourthly, a warning arises in that hypoglycaemic coma may occur after delivery if the dose of insulin is not reduced. The reduction should, of course, be made in accordance with frequent blood sugar estimations.

We are indebted to Dr. C. E. Lakin and to Mr. Comyns Berkeley for allowing us to publish this case, and to Dr. E. C. Dodds, the Courtauld Professor of Biochemistry, under whose direction the blood and urinary investigations were conducted.

PROTEIN THERAPY IN INSANITY OF PUERPERAL ORIGIN.

BY

VIVIAN BARKIN, M.R.C.S., L.R.C.P.,

ASSISTANT MEDICAL OFFICER, NAPSBURY MENTAL HOSPITAL, ST. ALBANS.

THE successful employment of protein therapy in a case of puerperal mania may well be a matter of general interest. The following clinical details of such a case suggests that it is possible in some instances to avoid the necessity of certification.

A married woman, aged 19, was admitted to Napsbury Mental Hospital on June 10th, 1926. Parturition had occurred six weeks prior to admission. There was no family history of insanity. The patient was very restless and confused, indifferent to her surroundings, incapable of giving any account of herself, and entirely influenced by hallucinations. About three months later she passed into the katatonic state, assuming peculiar attitudes, and exhibiting negativism. This condition was replaced about six months afterwards by one of excitement. She was continuously restless, noisy, destructive, abusive, obscene, very dirty in habits, and incessantly picked her skin. Occasionally she threw herself violently to the ground, sustaining various injuries. This state persisted, and there were signs of impending dementia.

Treatment.

On November 13th, 1927, the patient was put on a light diet: the intestinal tract was well cleared, and a minor degree of dental sepsis was treated. The cerebro-spinal fluid was under tension, but revealed no gross pathological change. The blood had an abnormal tendency to haemolysis and there was a mild degree of chlorosis. A stock mixed vaccine (T.A.B. 2,500 million per c.cm.) was used and a preliminary dose of 100 million was injected into the median basilic vein. The axillary temperature was recorded every half-hour; the maximum pyrexia (104° F.) was noted four hours after the injection, and the patient complained of intense headache; cyanosis was marked. This condition was maintained for twelve hours, after which the temperature gradually subsided and reached the normal at the end of thirty-six hours.

The intravenous injection was repeated on alternate days with gradually increasing doses of T.A.B. vaccine until fourteen injections had been given, the maximum dosage being 2,500 million. During this period a nourishing light diet was augmented by unlimited lemon juice and bland fluids.

Course of Mental State.

After the third induced pyrexia the patient was on the whole less restless and had occasional lucid intervals. She was very impulsive and occasionally threw herself out of bed. Later she had periods of confusion in the morning, which cleared towards noon. Her hallucinations were freely admitted and discussed, and she developed some insight into her condition. Her habits became clean and she abstained from the use of obscene terms.

The mental state of the patient improved; she began to take an active interest in domestic and other details, and she appeared to be convalescing, although she still admitted hearing "imaginary voices" at times. This abatement of her condition was short-lived, for while attending a patients' party she relapsed spontaneously into an intensely confused state. She became very restless, violent, noisy, destructive, obscene, and filthy in habits.

A second course of intravenous T.A.B. vaccine injections was given consisting of nine increasing doses, from a minimum of 125 million to a maximum of 5,000 million. The reactions in most instances were more severe than in the initial course; they were accompanied by rigors and marked constitutional disturbances. Her mental state at this time compared closely with that of a recent acute mania. She was very violent and aggressive, and had to be treated in a padded room owing to her frequent resort to self-injury and violence. This period of excitement persisted for several weeks, but gradually subsided. Since then a gradual improvement has been maintained. She has developed a bright and sensible manner, talks rationally, and takes a normal interest in her surroundings. She realizes her previous mental state, and her memory is good for recent events and for incidents which occurred prior to her mental breakdown. Her emaciated physical state has benefited considerably; her weight has increased by 3 st., an acneiform skin eruption and a seborrhoeic condition of the scalp have disappeared, and menstruation has recurred and functions normally. After a period of three months' convalescence under careful observation she was discharged recovered.

This history suggests that the intravenous administration of vaccines in a mental case, in which a toxic element is probable, appears to have a beneficial effect; that no very alarming signs or symptoms have resulted from these injections when used cautiously; and that the control of pyrexia is easily maintained. On one occasion a reactionary pyrexia of 105° F. occurred after the expected rise had subsided to normal. This was rapidly reduced by tepid sponging, and remained normal. Constipation was obstinate during the course of treatment, and was most effectually dealt with by daily bowel irrigation.

I am indebted to the medical superintendent, Dr. A. O'Neill, for permission to publish this case.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

ACUTE GASTRIC DILATATION ASSOCIATED WITH PULMONARY TUBERCULOSIS.

THE occurrence of acute dilatation of the stomach in a patient suffering from advanced pulmonary tuberculosis may be considered of general interest in view of the relative rarity of the condition and the uncertainty attaching to its etiology. The following clinical details of such a case may therefore be worthy of recording.

A young woman, aged 21, was admitted to the Osler pavilion, Radcliffe Infirmary, on August 21st, 1928, for the second time. Her illness had begun in January, 1924, with left-sided pleurisy. Since that date the patient had been in various institutions, in one of which, during 1925, artificial pneumothorax was carried out for six weeks. The patient was first admitted to the Osler pavilion on June 17th, 1927, and was discharged on November 11th, 1927. There was extensive disease in the left lung, but the right side was comparatively free from physical signs. On discharge, following sanocrysin injections and general routine treatment, the patient was described as being "much improved." Phrenic avulsion, or other surgical intervention, was refused by the parents.

On readmission, nine months later, the patient was obviously very ill. Considerable fever was present and there were frequent night sweats. For the first time tubercle bacilli had been found in the sputum at an examination shortly before admission. The physical signs on the left side were, if possible, even more extensive than at her first admission, and there were gross signs of infiltration and breaking down in the right lung in the neighbourhood of the angle of the scapula.

At noon on August 27th, 1928, the patient complained of fullness and discomfort in the abdomen, and vomited. The vomiting was repeated in the early afternoon, and the discomfort gave place to acute lancinating pain soon afterwards. The patient was then in a state of collapse. The abdomen was rigid but not tender, and there was no obliteration of the liver dullness. The pain was referred to the left of the epigastrium and later to the umbilical region. The bilious vomiting persisted and hiccup set in. Early in the day the bowels had been open naturally. Micturition and menstruation were normal and there was no history of a previous attack.

In the evening the patient was seen by my surgical colleague Mr. D. A. Abernethy, who has kindly supplied the subsequent notes of the case.

"Patient looks ill. Face anxious and drawn, tongue slightly furred, temperature 101° F., pulse 92, respirations 24. The abdomen moves poorly with respiration and is slightly distended generally, and tender over its whole area. On percussion there is a tympanitic area round the umbilicus, marked shifting dullness in both flanks and almost complete absence of liver dullness."

In view of these physical signs the diagnosis of a ruptured viscus was very naturally made and an immediate operation was deemed necessary.

"Under gas and oxygen anaesthesia the abdomen was opened by a right pararectal incision at the level of the umbilicus. An enormously dilated atonic stomach presented into the wound, and on rapid exploration no cause for this condition could be found. There was no constriction about the duodenum, and the superior mesenteric vessels were not occluding its third part. In view of the patient's general condition the wound was closed as quickly as possible, and a stomach tube passed; meanwhile about a quart of bile-stained fluid was drawn off and the stomach was washed out with two pints of sodium bicarbonate solution."

After the operation the patient survived for as long as eight days. A *post-mortem* examination was refused.

In the *Lancet* (1926, vol. i, p. 758) will be found a description by L. R. Shore of a case of acute dilatation of the stomach complicating artificial pneumothorax.

Reviewing the literature in the same article the writer noted that, out of the ten instances where intrathoracic disease was regarded as responsible for acute dilatation of the stomach (in a total of sixty cases), in one post-operative case pulmonary tuberculosis was found *post mortem*.

Oxford. WILLIAM STOBIE, M.D., M.R.C.P.

VIRULENT DIPHTHERIA AFFECTING FOUR MEMBERS OF THE SAME FAMILY.

THE severity of the disease which ran through this family, together with some of the points in the first case, seem to render the sequence of events worthy of record.

On September 17th, 1928, a boy, aged 15, complained of sore throat. A membrane developed over the fauces and tonsils, and there was great swelling of both sides of the neck. A nasal discharge developed a few days later. A swab was taken of the throat, and a small dose of combined diphtheria and scarlet fever antitoxin was given. The swab was returned negative to the Klebs-Loeffler bacillus. Progress was satisfactory, and by September 22nd the throat and nose were clear and the boy was regarded as convalescent. The next day he was not seen. On September 24th, the seventh day of illness, he vomited several times and became very collapsed. He was found to have a palatal paralysis and paralysis of accommodation, and his heart was beating at the rate of 30 per minute. He was treated with cardiac stimulants. The paralysis was not sufficient to interfere with swallowing, and nasal feeding was not necessary. The heart rate fell and remained below 25 until the end, on one occasion being as low as 18 beats per minute. On September 27th the rate rose to 24, but in the evening he died suddenly. The fact that he was fretting for his brother—who had died a week before from tetanus—and did not want to recover, was not in his favour.

On October 10th the family [illegible] for a change, leaving two girls here in [illegible] an aunt. The following day one of these girls, aged 9, developed a throat very similar to that of her brother. The swab in this case also was negative, but was nevertheless notified as diphtheria, and the child was removed to the fever hospital. She was given 16,000 units of antitoxin intramuscularly, followed by 4,000 units on each of the two succeeding days. She had a severe attack, and is now recovering from cardiac sequelae.

A sister, aged 7, in Birmingham, sickened on the same day as the previous patient, and on October 12th was admitted to the Birmingham City Hospital. Like her sister she had a "bull-neck." She was given an initial dose of 40,000 units intravenously, followed in two days by another 40,000, to which had been added 15 c.cm. of concentrated scarlet *fever antitoxin, since* she was regarded as having a double infection of diphtheria and streptococci. She is still under treatment at Birmingham.

On October 19th the father developed a throat which was at first thought to be a quinsy, to which he was subject. He was admitted moribund to the Birmingham City Hospital on October 26th, and died within twenty-four hours, *in spite of* vigorous treatment. The *post-mortem* findings were as follows: Diphtheria membrane was present on the throat and completely lining the larynx, trachea, and both bronchi. The bronchioles throughout the whole of the left lung were filled with membranous plugs. He also had an old mitral lesion, tuberculous scarring of both apices, and small granular kidneys. The membrane in this case formed a tree-like cast of the bronchi and some of the larger bronchioles, his condition being really one of diphtheritic bronchopneumonia.

It is rather interesting to note that the mother, a girl of 12, and a baby of 10 *months* escaped, as well as the aunt and her husband and child in whose house the second patient spent her first two days of disease.

The chief interest in the case of the first patient lies in the slow pulse. I have read that unconsciousness usually *results* with a pulse of 20 or under in cases of Stokes-Adams syndrome. This boy was never unconscious.

My thanks are due to Dr. E. H. R. Harries, *superintendent* of the City Hospital, Birmingham, for kindly letting me have details of the two cases which were treated in that hospital. I am also *indebted to Dr. Bonner for permission to publish the first two* cases.

Peterborough. L. B. PHILLIPS, M.B., Ch.B.

THE ELECTRO-MAGNET IN SURGERY.

THE following two cases emphasize the occasional value of a magnet in the removal of a minute and inaccessible foreign body, if made of steel.

CASE I.

A dental surgeon sought my help in the case of a young man in whom he had been producing novocain anaesthesia by blocking the inferior dental nerve. The minute needle had broken off, and was impacted in the region of the inferior dental foramen, between the internal pterygoid muscle and the ascending ramus, and presumably between periosteum and bone. In skiagrams the needle showed clearly.

Through a small vertical incision in the soft overlying tissues it could not be identified, either by sight, or by palpation with finger or probe. The nozzle of an electro-magnet was inserted into the incision, and the current switched on for about six seconds. On withdrawal the needle was adherent to the magnet.

CASE II.

I was asked by the operator to see a woman on whom he had performed a cortical mastoid operation five days previously. He had passed Stacke's guard into the aditus, to satisfy himself that he had really opened the antrum. Some hours later it was noticed that about 1/8 inch was missing from the fine distal end of the guard. Skiagrams in two planes showed the metal in the region of the aditus. I reopened the wound, but could not find the fragment. The magnet, fitted with an L-shaped steel termina], was inserted into the aditus; first from the antral side and afterwards, since there existed a total loss of membrane, from the middle ear. The steel fragment was removed, sticking to the magnet.

The electro-magnet, with terminals of various shapes, which can be boiled, was obtained from Messrs. Allen and Hanburys.

London, W.1. H. LAWSON WHALE, M.D., F.R.C.S.

IDIOPATHIC HAEMORRHAGE IN THE NEWBORN: RECOVERY AFTER TREATMENT WITH WHOLE BLOOD.

THE following case seems of sufficient interest to record, since such cases are rarely met with in general practice.

A primipara was confined on October 7th, 1928. Labour was normal, and the child, a boy, appeared to be quite healthy. Twenty hours later I was urgently sent for by the nurse. On arrival I found the child in a state of extreme anaemia and collapse, due to melaena *neonatorum* and haematemesis, which had suddenly started half an hour previously. Fortunately the father of the child was in the house, so that I was able to give the child parental blood intramuscularly within a few minutes of my arrival.

A 2 c.cm. hypodermic syringe was the only one available, but by filling it three times with parental blood 6 c.cm. of whole blood was introduced deep into the pectoral region of the infant. Hot-water bottles were applied, and *frequent sips* of a whey and cream mixture given to help to make up for the loss of fluid. A teaspoonful of the following mixture was also given hourly: Gelatin alb. 30 grains, sodium chloride 2 grains, distilled water 3 oz.

Six hours later, although no fresh haemorrhages had occurred, I thought it advisable to give a further intramuscular injection of blood. This time a 10 c.cm. Record syringe was used, and 10 c.cm. of the whole blood injected. The child made an uninterrupted recovery, and although the motions remained "tarry" for the next two days no fresh bleeding occurred.

In conclusion, I think the child's recovery was due to the following line of treatment: (1) intramuscular injections of blood were given at once; (2) whole blood was used, as advised by Dr. Cruickshank; (3) artificial feeding was started at once, and was continued until the arrival of the mother's milk, which was then pumped off and the child spoon-fed until he had sufficient strength to suck.

Wadhurst, Sussex. G. H. ROBERTS, M.B., B.S.Lond.

Reviews.

STUDIES ON SCURVY.

In their *Studies on Scurvy*[1] Professor ARTHUR W. MEYER and Dr. LEWIS M. MCCORMICK, of the Department of Anatomy, Stanford University, have provided a monograph of interest, not only to students of nutritional problems, but to physicians who seek for explanation of obscure conditions of ill health with which they have to deal in practice. The monograph furnishes another example of the widespread changes which may occur in various organs and tissues of the body as a result of diets deficient in vitamins.

The original object of these studies was "to ascertain, if possible, the causes of the appearance of peculiar phenomena in guinea-pigs kept on ordinary feeds and used in experimental anatomy. Among these phenomena were marked nervous manifestations and permanent, as well as profound temporary, locomotor disabilities." The animals did not appear to suffer from scurvy nor was the food on which they were fed suspected as being deficient until Professor Meyer had cured them by the subcutaneous injection of tomato juice, or by feeding some of the younger animals on tender lettuce leaves. Their marvellous recovery, following these measures, pointed to a dietetic origin of the peculiar symptoms from which the animals suffered. Experiments were accordingly undertaken to determine the nature of the responsible deficiencies. The experimental animals were given a basic diet of raw alfalfa hay, rolled barley, and water in abundance, which undoubtedly contained some anti-scorbutic vitamins. Some animals received this diet without its previous subjection to heat; others the same diet after it had been heated to 100° C. for an hour. The same lesions were produced, whether the diet had been heated or unheated; the only differences being that the lesions were more intense and their onset more rapid, while the point of death was more quickly reached, in those that received the heated food. Additions of wheat-germ (to increase the vitamin B content of the diet) or of dried whole milk (to increase the vitamin A content), or of both, to the heated and to the unheated diet, failed either to prevent or to cure the disease. It was concluded, therefore, that the responsible deficiency was one of vitamin C, and that the disease from which the guinea-pigs suffered was scurvy. The details of the experiments are scanty; but from a perusal of the 46 pages of the monograph dealing with the gross and minute morphology of the condition, it is evident that the changes which occurred in the various organs and tissues of the body are those known to be associated with deficiency of vitamin C. Some may doubt whether it be legitimate to attach the diagnostic label "scurvy" to a condition in guinea-pigs which did not present the classical signs and symptoms associated with this label. But the label is unimportant in itself; what is important is the fact that tomato juice and tender lettuce leaves cured the condition and dispelled a widespread state of tissue deterioration. It matters not what the condition be called, provided the cause be recognized and the simple means of its cure applied.

The authors describe anew the lesions noted to occur in various organs and tissues of the body by earlier workers on this subject; as well as some observations that are new—subcutaneous, muscular, pericostal haemorrhages; pulmonary, gastric, duodenal, caecal, vesical, and adrenal haemorrhages; and marked degenerative changes in cartilages, bones, teeth, muscles, many glandular organs, blood vessels, and also in the central, the peripheral, and the sympathetic nervous systems. The cytological changes in the blood are described; changes which became evident in guinea-pigs after ten days on the diet above mentioned. They consist in a decrease of the red blood cells, haemoglobin, and colour index, a relative decrease in the number of lymphocytes, an absolute increase in polymorphonuclears, and an increase in reticulated and nucleated red blood cells and leucocytes. It is to be noted that these changes in the blood, as well as others in the gastro-intestinal tract and urinary bladder, are definitely pre-scorbutic in their onset.

In laying down this monograph after a first perusal of it a number of impressions remain. How many are the obscure phenomena of disease which are traceable to faulty food: how well it is, in the experimental study of nutritional problems, to depart sometimes from the use of so-called synthetic diets deficient in (or supposedly deficient in) a single food factor, and to employ for such studies the ordinary food materials used by the man in the street or by the stock laboratory animal, in both of whom obscure phenomena of ill health so often appear; how instructive it is to work at times with diets which are not wholly lacking in a given food factor, but in which an insufficiency of one or of several is combined with food faults of another order, such as lack of balance in proximate principles; how closely intertwined in the exercise of their functions are the several vitamins; how necessary is an adequate supply of all of them to the maintenance of nutritional harmony, and how readily is this harmony disturbed by the insufficient supply of any one of them; how variable may be the reports of equally competent observers relating to a particular vitamin defect, and how much do these reports depend upon the composition of the diets and the age and strain of the experimental animals, as well as on the conditions of climate and altitude in which the different observers are working; finally, how important it is to recognize that complete deprivation of any vitamin is not a matter with which the physician is greatly concerned in practice, though he is often confronted with an insufficient supply of one or other or several of them in diets often faulty in other regards.

This monograph illustrates the fact that certain manifestations of ill health in guinea-pigs, which bore no close clinical resemblance to the classical picture of "scurvy," were definitely shown to be of scorbutic nature, and to be due to an insufficient supply in their diet of such foods as tomatoes and lettuce leaves. And if in guinea-pigs, why not in man?

R. MCCARRISON.

ANAEROBIC BACTERIA.

ALTHOUGH of the nature of a review, the work by Drs. WEINBERG and GINSBOURG on recent advances in anaerobic bacteria[2] is to be regarded as a supplement to Weinberg and Séguin's well-known monograph on the anaerobic bacteria of war wounds. The work contains analyses of the various publications which have appeared on anaerobic bacteria since the war up to 1926. The immense amount of labour entailed can be gathered from the fact that something like 1,200 references are cited.

The first part of the volume deals mainly with technical advances in the identification of anaerobes, and contains a list of all the new anaerobes described since 1915. Later the more important anaerobes—*B. chauvoei*, *B. botulinus*, *B. tetani*, *B. welchii*, etc.—are dealt with separately and in a very complete manner, including the various procedures suggested for the preparation of toxins and immune serums. Thus under *B. welchii* the newer researches on the relation of this microbe to pernicious anaemia are dealt with at some length.

This work, however, cannot be regarded in the same light as the original monograph on anaerobes by Weinberg and Séguin, but, even allowing for this, there are several points to criticize in the volume. In the first place its value would undoubtedly have been raised had the authors been a little more critical; researches obviously of widely different merit are treated with equal respect. This tends to make the survey colourless and not quite what was to be expected from workers with so much experience in this branch of bacteriology. The volume also shows a great indifference to the correct rendering of names. Moreover, there are a certain number of errors and omissions, as, for example, in dealing with the fermentation reactions as an aid to the differentiation of *B. chauvoei* from *Vibrion septique*, the authority cited is wrong, for the possibility of this was pointed out some

[1] *Studies on Scurvy.* By Arthur W. Meyer and Lewis M. McCormick. Stanford University Publications, University Series. *Medical Sciences*, Vol. II, No. 2. Stanford University Press, California. 1928. (Sup. roy. 8vo, pp. 107; 6 figures, 10 plates. Paper cover, 1.50 dollars; cloth, 2.25 dollars.)

[2] *Données récentes sur les microbes anaérobies et leur rôle en pathologie.* Par M. Weinberg et B. Ginsbourg. Monographies de l'Institut Pasteur. Paris: Masson et Cie. (Roy. 8vo, pp. 281. 35 fr. sans majoration.)

five years earlier in Report No. 12 of the Medical Research Council. No mention is made of the occurrence of *B. chauvoci* in human lesions, although a good deal of discussion has centred round this question.

A summary at the end states in general terms the most salient features of the works quoted. But we cannot agree with the view that the exact identification characteristic of *B. chauvoci* has not yet been settled, because the features of this anaerobe were clearly given in the two reports published by the Medical Research Committee (Council). The confusion that existed was due to the fact that *Vibrion septique* had not infrequently been mistaken for *B. chauvoci* owing to the former's presence in animal lesions, and also to the fact that the so-called Kitt strain of Rauschbrand circulating in Germany was, in reality, *Vibrion septique*. Again, the evidence brought forward in support of the view that *B. putrificus* is a separate identity is unconvincing. The authors have not attempted any form of systematic classification, which is perhaps wise in the present state of our knowledge.

This book, speaking generally, should prove of great value as a guide to the identification of the rarer types of anaerobic bacteria, and the authors are to be congratulated on having produced so important and useful a review of the subject.

BLUE SCLEROTICS AND FRAGILE BONES.

PART III of the second volume of the *Treasury of Human Inheritance*, edited by Professor KARL PEARSON, is devoted to the subject of *Blue Sclerotics and Fragility of Bone*.[3] The article is written by Dr. JULIA BELL. It contains, in the first place, a complete bibliography of the subject, which has evidently been carefully analysed by the author; secondly, a hundred pedigree diagrams, with very valuable descriptions of the members of each so far as they were obtainable, including details not only as to the occurrence of the two conditions under discussion, but also of all other associated anomalies; and, thirdly, a number of very fine plates illustrating the anatomy and clinical appearances of cases of blue sclerotics, fragilitas ossium, and osteogenesis imperfecta. The article embodies the whole of our present knowledge of the subject, and will take its place as the standard work of reference in future investigations.

In her introduction Dr. Julia Bell has drawn some interesting conclusions relating to the nature of the relationship between blue sclerotics and fragility of bone. Although the two conditions are relatively uncommon, they are well known owing to the distressing conditions exhibited in marked cases; for example, of one patient, suffering from fracture of the spine and ribs resulting from a fall, the family report that "they dare not take off the plaster lest she should fall to pieces," and an examination of some of the illustrations in the present volume shows that the fear could hardly be exaggerated in many cases. The presence of blue, or thin, sclerotics does not in itself produce any disability; the point of interest is whether, and how far, it carries with it a tendency to the graver condition of fragilitas ossium, and Dr. Julia Bell has addressed herself to the consideration of this problem in so far as the available material permits. It is only necessary to glance through the pedigree diagrams to satisfy oneself of the marked hereditary tendency to the occurrence of blue sclerotics; in No. 662, for example, the condition—[illegible] four out of five children and in eleven of the two succeeding generations. The importance of determining from cardiac sequelæ predispose to fragilitas

streptococci. She is still under treatment at Birmingham City Hospital.

On October 19th the father developed a throat which was thought to be a quinsy, to which he was subject. He was admitted moribund to the Birmingham City Hospital on October 26th, and died within twenty-four hours, in spite of vigorous treatment. *The post-mortem findings* were as follows: Diphtheria membrane was present on the throat and completely lining the larynx, trachea, and both bronchi. The bronchioles throughout the whole of the left lung were filled with membranous plugs. He also had an old mitral lesion, tuberculous scarring of both

ditions as independent, but linked together in such a way that the factor leading to the production of blue sclerotics merely predisposes to a faulty bone production. The theory of a double anomaly is suggested by the fact that there is no direct relationship between the severity of the two conditions, for very blue sclerotics may be unassociated with other defects, while less blue sclerotics may accompany a history of repeated spontaneous fractures. A further important conclusion drawn by the author is that in pedigrees showing associated defects of blue sclerotics, liability to fracture and deafness, the presence of blue sclerotics determines the addition of one or both of the allied defects in the descendants affected. In other pedigrees both conditions may occur independently in a hereditary form without blue sclerotics. Among the adult population of individuals affected with blue sclerotics approximately 60 per cent. have an associated liability to fractures, approximately 60 per cent. have an associated deafness, and 44 per cent. suffer from all three defects.

In enumerating the merits of Dr. Julia Bell's work we must not fail to mention the charming coloured portrait of "Peggy with the Blue Sclerotics," which forms the frontispiece to this attractive volume.

GONORRHOEAL ARTHRITIS.

A LARGE monograph of over five hundred pages on gonorrhoeal arthritis[4] has been written by a French surgeon, M. HENRI MONDOR. It is unusual for this disease, in Britain at least, to be treated by the surgeon, except to correct late deformities, and after medical treatment has come to the end of its resources. It is therefore interesting to read a surgeon's views on the disease as seen in all its stages, and to consider his summary of the forms of treatment which afford relief. M. Mondor declares definitely his hatred for the term "*gonorrhoeal rheumatism*," which he considers a poor and misleading name for one of the most severe and most destructive forms of acute arthritis known. He states that he has seen joint damage and destruction produced by the gonococcus in a few weeks such as the tubercle bacillus might take years to bring about. He draws attention also to the intensity of the pain in affected joints which surpasses in severity that of any of the other acute joint diseases.

Two interesting tables are given—one from the collected experiences of others and one from the author's personal records—to show which joints are most frequently involved. The knee-joints easily come first in frequency, and the wrist-joints second. Next in order of frequency come the os calcis, the cervical vertebrae, and the hip-joints, but the list seems to include almost every joint in the body. A full account of the pathology of the affected joints is given, especially of the destructive changes in cartilage and bone which may lead to ankylosis or to subluxation and dislocation of the joint. It is evident that of all the serious results the tendency to ankylosis is the worst; and in certain joints such as the wrist ankylosis is practically the rule. All the varying forms of treatment by drugs, vaccines of different kinds, and antiserums to the gonococcus are discussed, and the conclusion is reached that little trust can be put in any of them. M. Mondor is equally candid in admitting that surgical intervention, especially incision of the joint (arthotomy), is uncertain as a cure, and may be followed by progressive ankylosis and joint destruction just as after treatment by any of the other suggested remedies. What he does claim for surgery is immediate relief from the agonizing pain, rapid cessation of fever, and an immediate improvement in the patient's general condition, such as is effected by no other means.

Orthopaedic measures which may be necessary to correct gross deformities in old-standing cases are not considered in detail in the book, which concentrates on what can be done for the relief of the acute disease and the prevention of joint destruction. The drawings illustrating the pathology of the disease in joints are good, but many of the x-ray pictures are so poorly reproduced that they are quite useless to the reader, even when assisted by the descriptions given below them.

OPERATIVE SURGERY.

DR. J. SHELTON HORSLEY, of St. Elizabeth's Hospital, Richmond, Virginia, has lately published a third edition of his *Operative Surgery*.[5] The work serves a twofold purpose: it considers in detail the physiological and biological factors which underlie surgical procedure, and it affords a useful record of the author's personal operative experience. "Some Surgical Operations" would appear to be a more accurate title to the work, for the operations described belong to only two categories: those performed by the author, and those he personally regards as best adapted to the condition under consideration. The work must therefore be judged as one for post-graduates with a knowledge of surgery rather than as a textbook that would guide a candidate through the final fellowship examination.

All surgeons must perforce develop tendencies according to their interests and opportunities, concentrating on some aspects of surgery and paying less attention to others. Dr. Horsley shows in his book that he is no exception to this rule. For instance, undue space would appear to be given to plastic surgery and repair of aneurysms, to both of which excellent chapters are devoted, compared with the relatively slight treatment of such subjects as the ligation of arteries and amputations. The style in the chapters devoted to these latter is somewhat lax: precise landmarks for incisions are lacking, and in the general context there is an undue preponderance of "ifs." We do not think there would be any general agreement with the view expressed in the chapter on neurological surgery as to the use of fat grafts in operations for epilepsy; nor would we all agree with the author's opinion that the dura should be sutured in every spinal operation. In operating for peptic ulcer Dr. Horsley performs pylorectomy by stitching the duodenum to the lesser curve and leaving the "dangerous angle" below.

The illustrations to the book are excellent and numerous; the subject-matter is well up to date, and readers will find much of interest and profit within its covers.

NOTES ON BOOKS.

WE have received two short handbooks on the injection treatment of varicose veins. In *The Treatment of Varicose Veins by Intravenous Injections*[6] Dr. J. D. P. MCLATCHIE describes briefly the procedure and gives various practical hints. A good bibliography is appended. Dr. R. THORNHILL contributes a volume to the Minor Monograph Series on *Varicose Veins and their Treatment by "Empty Vein" Injection*.[7] The apparatus and technique are indicated and some illustrative cases are recorded. In a foreword Sir BERKELEY MOYNIHAN commends this method as a simple, safe, and quick device.

Dr. STRICKLER of Temple University, U.S.A., has produced a sound textbook on dermatology.[8] All the usual subjects are included and dealt with in an efficient manner. We have noticed no serious omission, although some of the chapters are rather scrappy. The chief novelties we have discovered are the diagnostic tables for those diseases of the skin, such as eczema, psoriasis, lupus erythematosus, etc., which are notoriously liable to give rise to difficulties of diagnosis, and many will doubtless find these schematic representations of the critical points of differentiation quite useful, although it must be remembered that there is no short cut to successful diagnosis and nothing that can be substituted for the daily work of examining and treating patients. Apart from this there seems no real reason why this textbook should have been written, seeing that there are already more than enough excellent textbooks on the subject. Dermatologists would be much better employed in writing monographs on special departments or diseases than in compiling general treatises which, although they often show signs of original and personal observation in some section which may happen to appeal especially to the author, must in the nature of things be principally drawn from previously existing works. No man can reap a good crop from the whole vast field of dermatology. Having entered this criticism we may add that Dr. Strickler's textbook is at least equal to most others. It is well got up and adequately illustrated. Most of the illustrations are good and clear, but there are a few which are not up to the general standard, and should be improved in the next edition, which will no doubt be called for in due course.

In continuance of its policy of encouraging post-graduate study, the Dental Board of the United Kingdom arranged, during the winter of 1927-28, a course of four lectures on *Radiology and Radio-therapy*,[9] which are now published under one cover. The physics of radiology are dealt with by Dr. G. W. C. Kaye, superintendent of the Physics Department, the National Physical Laboratory; instruments and apparatus, their construction and purpose, and radiographic technique by Dr. Robert Knox; the interpretation of dental skiagrams by Mr. H. M. Worth; and ultra-violet ray treatment by Professor Leonard Hill. The lectures maintain the high standard which the Board requires, and that by the late Dr. Knox will be especially valued, both for its technical value and as a memento.

SADTLER'S *Chemistry of Familiar Things*[10] is a book for the casual reader who, knowing nothing of chemistry as a science, would yet acquire some of the knowledge possessed by chemists. The author, an American writer, has avoided technicalities as far as possible, and has accordingly encountered the inevitable difficulty of conveying clear impressions without them, but he has mastered the difficulty in his own way, and very successfully; for, although his discourse contains many allusions to matters which are left unexplained, the main course of the text is easy to follow. It covers a broad range dealing with the relationships of the elements, natural phenomena, industrial and physiological chemistry, foods, and hygiene. A good deal of useful information is given about the percentage composition of foods and other data, as well as sundry matters of curious interest, such as directions for silvering glass. It is altogether a readable and instructive book, but we must protest at the sentence which reads: "A German physicist, Robert Mayer, found a value that constituted the mechanical equivalent of heat." Surely the name of Joule is not unknown in America.

The Very Thing,[11] by FRIDA WOLFE, is essentially curative, and it may therefore be said to have established a claim for notice in the austere columns of a medical journal. We are all called on to deal with fractious children every now and then. Here is a remedy. The delightful child verses, read aloud by the right sort of mother or aunt, are guaranteed to cure the very worst case of fractiousness. Little woodcuts by Elizabeth Rivers add to the attractions of a charming nursery book.

PREPARATIONS AND APPLIANCES.

MENISCOTOMY KNIFE.

MR. H. A. T. FAIRBANK, D.S.O., M.S., F.R.C.S., writes: Accurate division of the posterior end of the so-called bucket-handle lesion of a semilunar cartilage, close to its attachment to the bone, is difficult or impossible with a straight tenotome or other knife. The advisability of dividing the cartilage close to the tibia arises from the occasional finding of a tag at the back of the joint, with its sole attachment to the rest of the cartilage close to the bone. To avoid such a tag being missed the dividing knife must cut close to the bone in an oblique plane. The curved end of a

FULL SIZES

Macdonald's dissector has been found a useful instrument for determining the precise direction in which the knife should cut. Messrs. Allen and Hanburys have made for me a knife with a similar curve, a probe point, and a short cutting edge, and this has been found to answer the purpose admirably. Since it is wiser not to use a double-edged knife inside the knee-joint, the knives are made in pairs, to cut to the right and left respectively. Experience has shown that these knives are sometimes useful in knee-joint surgery for purposes other than that for which they were designed.

CITIZENSHIP AND CIVILIZATION.

SINCE 1902 the Yale University Press has been publishing at intervals in book form the Yale Lectures on the Responsibilities of Citizenship. The latest of the series is *Citizenship and the Survival of Civilization*,[1] by Sir George Newman, and it is described as being based upon the Dodge Lectures he gave last year at Yale University. The text is doubtless modified and amplified a little from what was actually spoken, and the prologue and epilogue, each of notable beauty, are probably new. The whole volume is such as the medical profession and the thoughtful reading public have now learnt to expect from Sir George Newman—scholarly, well arranged, suggestive, and enlightening. The field surveyed is immense, almost all-embracing, and to have accomplished so much in little more than two hundred pages, with sufficient breadth of view to make it comprehensive, with sufficient system to make it intelligible, yet in sufficient detail to make it interesting and practical, is no small achievement.

Sir George Newman's political philosophy, expounded as the basis of his position and traced from its more remote origins, is not that the individual exists for the sake of the State, which is the fundamental creed of Fascism; or of the Class, which is that of Communism, and, in practice, of too many socialists, though not necessarily of Socialism. It is rather that of T. H. Green, who "believed in the essential work and divinity of the individual, upon whose moral and spiritual growth everything depended; behind the individual was the State, an organization for the liberation and education of this moral individual; behind the State he visualized an eternal mind or supreme consciousness which reproduces itself as human personality"; and who claimed that "good consists in the realization of personality which can only be reached in some society of persons who, while remaining ends in themselves in the sense that their individuality is not lost but rendered more perfect, find perfection only attainable when their separate individualities are integrated as parts of a social whole; the law of our being, therefore, involves the growth of personality with civic and communal duties." Citizenship is regarded as a number of different but not incompatible loyalties, harmonized in one living addition to a common interest which makes human life purposive so far as it is not of undirected or misdirected. These harmonizing loyalties to self, family, profession or trade, science, art, etc., are leading on to a yet wider culture which is civilization. There its cultivation, emancipation, and social insurance are education and in education.

Meanwhile, in the body politic there are only too evident vestiges of a different philosophy—the dominance of the economic factor in society, the materialistic measurement of success and interpretation of history, the extravagant claims of the superman, the apotheosis of force. These incompatibilities have to be removed more or less drastically, and there are a large number of other disharmonies which have to be reconciled in order to accomplish or complete the emergence into civilization. Such are those due to the overpopulation of localities and to the mixture of races, those which in the body and mind of man arise from physiological neglect and a misunderstanding of eugenics, those connected with maternity and infant upbringing, and those due to unwisdom in personal hygiene, whether bodily or mental.

Sir George Newman has a very interesting chapter on "Disease in history," which contains lessons for the historian, the sociologist, and the general reader. Here, more perhaps than anywhere else in the book, does the author direct his erudition and his idealism to the service of practical ends. He founds his faith in the future of preventive medicine on the growing synthesis of mutual aid, communal co-operation, and mental development. "Our objective," he says, "must be not a longer life only but a better one—an enlarged, enriched, emancipated life, full of work and search, inspired by loyalty and hopefulness, with a forward-looking mind." It is in this spirit that the whole of the book is conceived. If, here and there, the smooth steps of the discourse seem to halt a little, or if the exact logical reason for fitting some section into its particular niche escapes us, the work, both as a whole and in its several parts, is a fine scientific and literary accomplishment.

FRACTURES NEAR THE WRIST.

Two years ago we discussed a paper by Mr. Harold C. Edwards on backfire fractures, in which were set forth the particulars of forty-two cases treated in the fracture department of King's College Hospital.[1] A study of these cases went to prove that backfire fracture is not a clinical entity; that is to say, that it is not to be distinguished clearly from other fractures of the radius, and that the nature and exact site of the injury appear to vary just as much as they do in other fractures in this region. This is hardly surprising seeing that, as Mr. Edwards has pointed out, backfire fractures are not all produced in the same way, for some are due to indirect and some to direct violence, while the mechanism of some others is obscure. In their paper on fractures of the lower end of the radius in adults, which appears at page 61 in our present issue, Mr. Edwards and Dr. E. B. Clayton describe and discuss 424 cases of fracture, among which are included various fractures of the radius, but of which the vast majority are Colles's and backfire fractures. As these cases were all treated at King's College Hospital in the three years 1924–1926, we may assume that the forty-two previously recorded cases are among them, as well as forty-two other backfire injuries.

The sex incidence of these injuries is interesting, for while only one backfire fracture was suffered by a woman, 250 of the 339 cases of Colles's fracture—that is, nearly three-quarters—afflicted the female sex. Indeed, Colles's fracture might almost be called the "women's fracture," since the male sex suffers fracture of other parts of the body far more often

On October 19th the father developed a throat ...urture as first thought to be a quinsy, to which he was subject. ...e free admitted moribund to the Birmingham City Hospital on ... 26th, and died within twenty-four hours, in spite of vigorous treatment. The *post-mortem* findings were as follows: Diphtheria membrane was present on the throat and completely lining the larynx, trachea, and both bronchi. The bronchioles throughout the whole of the left lung were filled with membranous plugs. He also had an old mitral lesion, tuberculous scarring of both

than the female. These statistics bring out also the prevalence of a backward tilt of the lower fragment in the vast majority of impacted Colles's fractures, and the authors of the paper rightly lay great stress on the importance of correction of this angular displacement, which, if allowed to remain, upsets the whole modus operandi of the joint. Correct replacement of the joint surfaces in their normal relation to one another is of far more importance than restoration of the exact contour of the shaft of the radius; indeed, without the former a good functional result is not to be hoped for.

There has been some difference of opinion among surgeons as to the importance of anatomical correction in fractures, which may perhaps be explained by supposing that they have not all meant the same thing by this term. In a discussion on the treatment of recent fractures by operation, held last spring in the Orthopaedic Section of the Royal Society of Medicine,[1] two most distinguished surgeons expressed different opinions on this matter, Dr. Charles Scudder of Boston saying that exact anatomical correction was of the first importance, while Sir Robert Jones maintained that a good functional result was the ideal to be aimed at, no matter what deformity persisted. Yet no surgeon has insisted more upon the importance of accurate anatomical correction of Colles's fracture than Sir Robert Jones, and, as Mr. Edwards states, good end-results are only to be hoped for when his teaching is strictly followed and the backward tilt of the lower fragment of the radius converted into the slight forward inclination which is anatomically normal. We take it that any apparent discrepancy in the views of two such eminent and experienced authorities on this matter is not real. Both would agree that in fractures involving joints or disturbing their alignment the most exact anatomical correction is desirable, and neither would deny that in fractures not involving interference with articulations a thoroughly good functional result is often compatible with some gross deformity, which it is not necessary to correct by operation.

The statistics of these 424 cases are of considerable interest, yet, like all statistical statements, they might mislead if not carefully interpreted. For instance, they might be taken as showing that the goodness of the end-result was in inverse ratio to the length of splint treatment, yet this inference is at once upset when we reflect that the less serious cases were the soonest released from splints. Extended experience seems to have confirmed the opinions as to the value of massage and the stage at which it should be used, which Mr. Harold Edwards expressed in his former paper. He and Dr. Clayton designate 12 cases, or 3.7 per cent. of the total, as bad results, and present them in tabular form. This table is very instructive as an indication of what to expect. Three of these cases had osteo-arthritis before the injury, others were old cases or unusually severe. Among these 12 were 2 cases of double Colles's fracture, in each of which there was a perfect result on one side but an imperfect result on the other, and this difference was in each case clearly due to insufficient correction at the outset. In falls on the hand, such as caused the 339 Colles's fractures, the force is not all expended on the wrist and forearm, but considerable violence may also reach the shoulder. We are therefore surprised to find no mention of obvious shoulder injury, although it is stated that early in the physiotherapeutic treatment the shoulder movements are tested. It would be of interest to know whether in any case shoulder-joint trouble of late onset occurred, such as some surgeons have attributed to contusion of the cartilage of the glenoid cavity.

This paper is most instructive, and it deserves careful study by all who have to treat fractures. Such a piece of work shows the value of a fracture department of a general hospital, and its publication gives us an opportunity of expressing once again our hope that the example of King's College Hospital, and of some other hospitals in the provinces as well as in London, will be generally followed as regards the treatment of fractures.

[1] *British Medical Journal*, April 14th, 1923, p. 656.

INFLUENZA.

THE Ministry of Health has issued to sanitary authorities in England and Wales a circular (No. 955) bringing to their notice the fact that during the last few weeks a very rapid spread of influenza has been reported from the United States and Canada. It is therefore considered advisable to call the attention of local authorities to the revised Memorandum on Influenza (Memo. 2/Med.) which was issued to them in January, 1927, when an epidemic of influenza occurred in this country after other countries had suffered a similar visitation. This memorandum, which contains the principal considerations to be taken into account by local authorities in the event of a sudden increase in the prevalence of influenza, was the subject of a leading article in our issue of January 29th, 1927 (p. 202), when we commended it to the notice of all concerned. It deals concisely with the history and nature of the disease, describes suitable measures of personal protection, and gives details of the action to be taken by sanitary authorities to combat outbreaks. The concluding sentence states: "The most important services . . . consist in the organization of the available nursing service and the provision of assistance to influenza-stricken households." In the Ministry's circular local authorities are reminded that in the event of an outbreak the Minister's general sanction has already been given to the provision by them of medical assistance (including nursing and the dispensing of prescriptions) for the poorer inhabitants of their districts who are suffering from the disease. Copies of the memorandum may be obtained from H.M. Stationery Office, or through any bookseller, price 2d. net. The recent epidemic which swept through the United States has led to the appointment by the Surgeon-General of a special sanitary board to advise the public. In Berlin, according to press reports, a very widespread epidemic of mild influenza is being experienced. It is stated that the hospitals can admit no more than about 35 per cent. of the cases reported to them by the sick funds, and that only those cases complicated by pneumonia are being accepted. One estimate of the numbers affected places the total at about 100,000 in the city, and about 4 per cent. of the employees in the municipal offices are believed to be suffering from the disease.

THE DOCTOR AND THE NEXT WAR.

BRITISH faith in the possibility of "muddling through" in all conceivable circumstances has received many rude shocks since the end of the nineteenth century, when this complacent doctrine was most widely accepted, and it seems reasonable to suggest that after four years of war and ten of troubled peace the general lack of interest in "preparedness" arises rather from a feeling that human foresight is vain in the face of fate than from any deep confidence in our ability to master the course of events as they arise. Dr. Leonard P. Lockhart of Beeston looks with some concern on the ostrich-like policy of hiding our heads in the

hand at the mention of anything connected with war, and of ignoring the new problems of national defence; he has accordingly devoted himself to a study of the situation to be faced by the civil population in the event of its exposure to gas attacks from the air, and has set forth the results in an article entitled "Chemical warfare and the medical profession" in the January number of the *National Review*. Dr. Lockhart makes no claim to originality, and at least one of his points—that treaties and conventions and protocols offer no definite security against the use of gas—will probably be generally accepted. His second point (based in great part on the argument in Mr. J. S. B. Haldane's *Callinicus*), that poison gas is a less cruel and less disabling weapon than shrapnel and high-explosive shells, is one on which many members of the medical profession who saw active service in the war will be in a position to pass a reasoned judgement. Dr. Lockhart finds statistical corroboration for this view in the fact that towards the end of the war, when troops were adequately protected and trained in anti-gas measures, the mortality among casualties from high-explosive shells was 25 per cent., while among gas-shell casualties it was only 3 per cent. He is anxious, however, to emphasize the great demoralization likely to be caused by gas attacks—and, it might be added, by the immediate threat of gas attacks—and to urge that the public must be educated in the need for, and means of, defensive organization. It is his considered opinion that "gas is going to be used in the next war for precisely the same reason that the Chicago police use it—it works." Dr. Lockhart argues in effect that the advantages which it offers as a weapon will make the temptation to use it irresistible. The ease with which civil chemical plant can be converted for the production of "war" gas, the facility with which commercial aircraft can be equipped to launch it in enemy territory, and the possibility of employing this mode of attack immediately war has been declared, give it the ideal military quality of surprise. The fourth element, with which he is most closely concerned, is the dilemma in which civilian medical and [illegible]tal authorities will find themselves when faced with an [illegible]l gas attack in their area with little or no previous [illegible]arning. He pleads, therefore, for the instruction of the public, so that they may realize that with proper measures they will have little to fear, and for the preparation of defensive schemes. He then reviews the modern chemical agents used in war, and gives a summary of a suggested defence scheme formulated by Squadron Leader A. P. Lawrence, director of medical services in the Royal Australian Air Force. This scheme embodies much useful information about practical anti-gas measures, and outlines the framework of a civil anti-gas organization. It is assumed that "gas masks for all" is an impracticable suggestion, and that political considerations will in time of peace prevent the wholesale dissemination of information among the public. All local authorities, and police, fire brigades, and medical personnel, should, it is suggested, be carefully instructed in their duties, and should be informed of their place in the defensive organization. In the proposed system of control the main executive authority is placed upon the chief constable in each area, the medical officer of health being in a position of great responsibility with the duties of co-ordinating ambulance and hospital services, instructing the staffs in their duties, arranging for protected buildings in congested areas, providing for "decontamination," and securing the purity of food and water supplies. It is suggested that consideration of the possible results of an attack may lead to the removal of hospitals from central urban areas. Dr. Lockhart believes that civil gas defence as a branch of State medicine will sooner or later become part of the medical curriculum, and contends that in the meantime nothing can relieve the medical profession from the duty of being ready to treat the casualties of chemical warfare. It may well be questioned, however, if the proposed organization will necessarily be as effective as Dr. Lockhart suggests. Dr. Lewin, toxicologist to the University of Berlin, at a recent conference convened at Frankfurt by the Women's International League for Peace and Liberty, stated that there were to-day twenty-five varieties of poison gas against which all antidotes and protective measures were virtually valueless. He was supported in this view by Dr. Steck, chief of the Swiss Federal Office for Protection against Gas, and by Herr Nestler, a German gas officer during the war, who said that all forms of defence of the civilian population were either too expensive or inadequate, or both. Dr. MacCartney, speaking at the same conference, shifted the responsibility for prophylaxis from the doctor to the chemists. The chemists, he said, were responsible for the production of poison gas; the protection of the public against its ravages was therefore primarily their concern. The remedy he suggested was that the chemical industries should be subjected to control. From these views some may draw the pessimistic conclusion that in face of chemical warfare medical science is likely to prove of little avail; most doctors will rather conclude that there is need for redoubling their efforts to discover means by which the effects of the new weapons of warfare may be successfully countered. In the words of a writer in the *Journal of the American Medical Association*: "Human protection and relief cannot complacently await the millennium, when warfare will have been relegated to the background of antiquity and abandoned atrocities."

THE MARCH OF PHYSICS.

EVERY year the Physical and Optical Societies unite for an exhibition of recent developments in their respective fields. The exhibition this year, which was held at the Imperial College of Science, South Kensington, from January 8th to 10th, was the largest in the nineteen years' history of this event. It was divided nominally into two sections—one research and experimental, the other trade. In actual fact the methods and results of recent research in physics were illustrated as elaborately in the exhibits of some of the commercial firms in the trade section as in those of the National Physical Laboratory in the other. Looking round the exhibition one got an impression that the present "push" in physics is in the extension of the domain of the ear rather than of the eye, for everywhere the wireless loud-speakers, the automatic gramophone, and the public speech amplifier were roaring like giants. Yet the optical exhibits, quiet as they are in comparison, never cease to fascinate, and here was an array of microscopes and telescopes, epidiascopes and cinematograph projectors, photographic lenses and prism binoculars, more highly specialized than ever. The historical section, with its relics of some of the old opticians, was as engrossing as usual, and the Wheatstone stereoscope was still an attraction. Among the exhibits were a number of photomicrographs, chiefly of biological and histological subjects, the work of Dr. C. L. Martin and Mr. Johnson, taken by ultra-violet illumination through an optical system entirely of quartz. Dr. E. W. Scripture, now professor of experimental phonetics in the University of Vienna, showed interesting apparatus for the registration of speech, including some charts illustrating the speech in various conditions of aphasia and dysarthria. By his apparatus both the fine vibrations, which are transmitted and heard in the voice, and the mass air movements, which are not transmitted or heard, are made to move a diaphragm of oil-silk, the vibrations of which are registered on the moving surface of a recording drum. Such substitution of accurate measurement for the somewhat vague judgements of the ear has obvious educative value; it may even find diagnostic

application. The large exhibit of the Meteorological Office included a sky photometer for determining the visual intensity of daylight during gloomy periods, such as those accompanying high fogs; an instrument called a psychrometer, for measuring temperature and humidity on aeroplanes used for meteorological observation; and a wind direction recorder actuated by electricity.

OUR HOMES.

THE architect does not often resort to the pen: he is mostly content to let his work make its own appeal. And whose work has a greater and more lasting appeal than that of the good architect, or whose work brings down upon his memory more anathemas from those who have to put up with it than the work of a bad architect? Mr. Gordon Samson is both an architect and an author. His latest book, *Houses Planned for Comfort*,[1] is designed to make a special appeal to our profession. "Many, probably most, of us," he says, "can never repay the debt we owe to those kindly wizards called doctors, who, called in when we are ill or broken down, mend us with marvellous skill and send us on our way—more or less rejoicing. But the houses in which we live generally work against, and not with, the efforts of our kind wizards (through faults and omissions which could easily be avoided in the initial planning of every house), and this to such an extent that when old age or chronic illness overtakes—as sooner or later it always does overtake—some member of the family, much that the doctor could do in prolonging the life and powers, the usefulness and happiness, of the patient is frustrated by the fundamental faultiness of the arrangement of most houses." The aim of this book is to show how, with a little care and forethought, these faults can be avoided. The directions are sound and eminently desirable of attainment. But, alas! the world is not large enough for all of us to attain these advantages. "Where the subsoil does not happen to be rock, gravel is the best. Clay, as it retains the water, is the worst, in that respect, that you can build on." If clay be barred, then we must pull down most of London, and much of England, for the clay is always with us. We have learned of the virtues of the southern aspect, and lament that so many delightful old houses, so desirable in their dignified antiquity, show that our forefathers cared for none of these things. But when the author advises his readers to "avoid building on sites where the sunshine could, at some future date, be cut off from you by high buildings or by high trees," we feel we must migrate to the illimitable spaces of the high veld of South Africa, for this security cannot be found by those who have to work in England; not even is the social Olympus of Park Lane exempt from such dangers. Mr. Samson is at his best in his exposition of the internal fittings of houses, and there is much sense in his plea that at least one bedroom in every house should be so fitted that it can be used effectively as a sickroom in case of need. There still lingers a preference for being at home rather than at "a home" when one is sick, and every doctor must have deplored the inadequacy of the otherwise well-provided house in respect of the simplest conveniences for nursing. Mr. Samson shows how this lack may be supplied with ease, though we are not entirely at one with him in his love of electrical gadgets, for when these are not in constant use they are apt to be out of order when wanted. This is a book well worthy of study, and the illustrations make it intelligible to the least technical of readers. It is dedicated to the memory of Dr. George Charles Bright, who died at Cannes in 1922, aged 82 years.

[1] *Houses Planned for Comfort, and with Special Conveniences for Invalids and the Aged.* By G. Gordon Samson, Architect. London: Crosby Lockwood and Son. 1928. (6 × 9¾, pp. xv + 191; 8 plates. 8s. 6d. net.)

QUACKS OF OLD LONDON.

IN a pleasantly written and well-illustrated volume Mr. C. J. S. Thompson, lately of the Wellcome Historical Museum, who is the author of a number of other interesting books dealing with certain aspects of medical history, tells the story of *The Quacks of Old London*.[1] Human nature and credulity remain much as they always were, and so the conditions have ever been favourable for mystery-mongering and quackery; but in the Middle Ages there was no real line between the regular practitioner and the pretender to the art of healing. Little is known about the quack doctors who began to flourish here about the sixteenth century, in spite of the Act passed in 1511 in order to suppress them. Two centuries later they were enjoying their golden age in this country, which has been called their paradise; it was then that one of them, William Read, was sworn-oculist to Queen Anne, who knighted him in 1705, and to George I. Roger Grant and John Taylor, "ophthaliator," in due course succeeded Read as quacks in this line of advertised activity. A royal protégé, Joshua Ward, was so successful in curing the pain in the thumb of George II that he received a vote of thanks from the House of Commons, and was protected from any interference by the College of Physicians with his practice. The account of Mrs. Mapp, or "Crazy Sally," the bone-setter, who was "all the cry" of the town at one time, but took to drink and died miserably near Seven Dials, is enlivened by some contemporary verses in her praise. Instances of the absence of honour among quacks are given: for example, Mrs. Phillips of the "Green Canister" in Half Moon Street, Strand, made a fortune by selling contraceptives and retired; a rival then personated her, and when the real Mrs. Phillips returned to the trade there was a struggle of advertisements. Early in the sixteenth century the Royal College of Physicians was founded, with a charter conferring powers to summon quacks before it and imprison them; but though these powers were exercised the evil grew all the same. Mr. Thompson traces the history of quackery from Tudor times to the end of the eighteenth century, giving many examples of the activities of charlatans and their bills of advertisement. Moses Stringer, who appears to have knighted himself, proclaimed that his *Elixir Renovans* would cure old age and the gout; like Mrs. Phillips, a rival spread abroad the announcement of his death, and so led to the not unnatural protest on Moses's part that the announcement was premature. This interesting "Who's who" of metropolitan quacks of a bygone age—and they have too many present-day successors—contains also accounts of bagnios, cuppers, and beauty specialists, and is a book the public would do well to read, mark, and inwardly digest.

JEWISH HEALTH ORGANIZATION.

THE fourth annual report of the council of the Jewish Health Organization of Great Britain is a document entirely without frills. It presents a terse, almost laconic, statement of the work of the various committees of the organization during the past year, but makes no attempt to point a moral or adorn a tale. The organization promotes health education by means of lectures and publications, by instituting an annual Health Sabbath in connexion with the Health Week of the Royal Sanitary Institute, and by arranging health exhibitions. It has set itself the task of studying systematically the health and diseases of Jews and non-Jews with a view to discovering what, if any, are the factors of race and of custom determining the differences in the incidence of certain diseases. To this end Dr. M. Sourasky has investigated cancer diseases among Jews,

[1] *The Quacks of Old London.* By C. J. S. Thompson. London: Brentano's Ltd. 1928. (Demy 8vo, pp. xvi + 356; 35 illustrations. 12s. 6d. net.)

and has produced evidence, first submitted to the International Cancer Conference in July (*British Medical Journal*, July 26th, p. 171), suggesting that there is no reason to believe that Jews are either more or less liable to cancer than other races. On the other hand, the relative immunity of Jews from cancer in individual organs —for example, in the penis and the uterus—deserves consideration in relation to prevailing Jewish social and hygienic customs. A comparative study of visual defect in non-Jewish and Jewish children, undertaken by a committee of ophthalmic surgeons appointed by the council, showed that in a large group of boys in the East End of London the percentage of Jews with visual defect was about twice that of non-Jews. The committee believes that this difference is determined, not by intensive school work among Jewish children, but by a racial factor. The results of a carefully planned investigation of the comparative intelligence and attainments of Jewish and non-Jewish school children are also included in the report, and appear to bear out the common belief that up to the age of 13 the average mental ratio of the Jewish child is greater than that of the non-Jewish child, though investigations of groups of older children would appear to be desirable. An important activity of the organization is child care and guidance. Just over a year ago it established an undenominational child guidance clinic, and up to the time of the issue of the report had dealt with 63 cases. The clinic was open on 104 evenings, and during that period there were 309 attendances of patients. Those who know how much time must be occupied in the study and treatment of each individual case in such a clinic will realize what a record of work these figures indicate.

BIRTH CONTROL CLINICS

THE North Kensington Women's Welfare Centre gives advice on birth control to women unable to afford the fees of a private medical practitioner. The fourth annual report just published gives a record of work for the year ending July 31st, 1928, during which period 1,183 visits have been paid by patients to the centre at 12, Telford Road, Ladbroke Grove, W.10. The policy of this organization is to discourage women from using contraceptives until they have had at least one baby, and to suggest the advisability of having more than one. A medical supplement gives a useful account of the experience of the centre as to the relative efficiency of various contraceptive devices. In the preface to the annual report of the Society for the Provision of Birth Control Clinics (153A, East Street, London, S.E.17) the fact is emphasized that in the distressed mining areas the infant population is still growing almost as rapidly as in times of prosperity. "There is no visible outlook in life for these children, and both husband and wife would be relieved of a heavy load of anxiety if they were taught sound methods of avoiding unwanted conceptions." This society, which now works through twelve centres in London, the provinces, and Scotland, aims at giving such instruction, and a noteworthy aspect of its work is the establishment of a clinic in a Midland mining area. The report observes further that many miners' wives attend the Glasgow clinic. During the year 3,914 new cases have been dealt with by the various clinics, 1,377 by the society's pioneer centre at Walworth, and there have been in addition 7,606 return visits (3,250 at Walworth). A recent analysis of the first 5,000 cases on the books at Walworth has revealed some matters of special interest. Of these 5,000 women, 315 were found to be pregnant on the first visit, and have not returned; 18 sought advice for sterility; and 32, of whom to date 31 have attained their wish, discontinued using contraceptives so as to have a baby. Many years must elapse, however, before any definite conclusions can be drawn as to the effect of the practice of conception control on the incidence of child-bearing among a given set of patients.

THE seventh British Congress of Obstetrics and Gynaecology will be held in Dublin on April 24th, 25th, and 26th, 1929, under the presidency of Dr. Gibbon FitzGibbon. The chief subject for discussion is "Disproportion," and there will, in addition, be numerous papers on matters relating to obstetrics and gynaecology. An exhibition of pathological specimens will be arranged. It is hoped to have a representative gathering from all parts of Great Britain and Ireland. Those wishing to read papers, and those who hope to be present at the congress, are asked to communicate as soon as possible with either of the joint honorary secretaries, Dr. Bethel Solomons, Rotunda Hospital, Dublin, or Mr. Gerald Tierney, F.R.C.S.I., 22, Lower Baggot Street, Dublin.

THE KING'S ILLNESS.

TAKEN as a whole, the brief bulletins issued from Buckingham Palace during the past few days have pointed to a slight but not negligible improvement in the King's condition, after seven weeks of an extremely acute illness. This is in accordance with the carefully worded estimate given in the medical communiqué of Wednesday, January 2nd, which appeared at page 31 of our last issue. With exhaustion of body and mind remaining so conspicuous a feature of the case, progress cannot but be slow and difficult. All that has been said in recent reports about the great weakness, the wasting, and the trouble with feeding will obviously hold good for some time to come; and therefore, as every doctor must realize, the position is still by no means free from anxiety. Early and smooth convalescence is out of the question after a streptococcal septicaemia associated with empyema in a patient well on in middle age.

No further communiqué has been authorized for publication in the medical press this week, but our readers will gather from what follows that His Majesty is making as much headway as can be expected at this stage of his long and grave illness. Since the beginning of the New Year the upward steps towards recovery have, we believe, outnumbered the steps down. The empyema wound is healing very satisfactorily, and the chest symptoms are now regarded as of secondary importance. We learn also that the pulse rate has improved and is less easily disturbed.

Estimations of the urea content and the calcium content of the blood, and other biochemical analyses, are being made at intervals by Professor E. C. Dodds, whose signature appeared on the evening bulletin of January 1st. We regret that in this matter, as in one or two others bearing on the King's illness, so much random speculation should have been indulged in of late by a few of our non-medical contemporaries. It contrasts unfavourably with the restraint of the newspapers as a whole throughout all the earlier and more trying phases of a situation without parallel in the history of the press. Irresponsible and wildly erroneous guesses are unfair to all those of our profession who are sharing the heavy task of attendance upon His Majesty, and not least to the colleague whose name has had this unsought publicity in connexion with one of the many therapeutic measures employed during the past two months.

THE HEALTH OF THE SCHOOL CHILD.

ANNUAL REPORT FOR ENGLAND AND WALES.

THE Annual Report for 1927 of the Chief Medical Officer of the Board of Education,[1] Sir George Newman, is a document of much interest, and it is one which should be read, not only because it is a storehouse of facts regarding the growing generation, but because it is inspired with a wide view of what is of the highest value in national well-being. It is a book that should be widely read, both by doctors and laymen.

The facts are derived from the examination of some two million children. In this country, where in normal times there is no conscription and therefore records of such massed medical examinations are lacking, there is no more convenient and comprehensive means of evaluating the health of the people than through the school children. But the true purpose of school medical work is not merely statistical; it is to ensure that the children shall be in a fit state of health to take advantage of the schooling provided for them. It is futile to spend vast sums of money on the education of pupils who are unable, on account of physical or mental defect, to reap advantage from it.

The report opens with a lively picture of the work of the school medical staff, first in a country school and then in a town school. To the casual eye of the untrained visitor the children in each school may seem blooming and healthy. To the trained eye of the doctor and school nurse, with their high standards of health and efficiency, are visible defects, both inherent and acquired, which are detrimental to the child. The systematic medical inspection of children is heavy and exacting work, but absolutely necessary. It is the grand inquest of the nation, the sole means of discovering and then strengthening the weak points of the individual child. By dealing with the individual the national health is built up. In former days the utmost ideal lay, in Milton's words, with the general "betterment of man's estate"; now the ideal is the betterment of man. Sanitation is surpassed by social evolution.

School medical work makes practicable a fuller education of the people as a whole; it adds to life "the joy of those who are healed"; it is the prelude of national efficiency. The science and art of medicine have contributed substantially, not to say immeasurably, to the higher evolution of school life. It was the apostles of medicine who demanded more warmth, light, and air in the schoolroom, who made evident the need for the practical teaching of hygiene, who proved that the child must be fed before it could be taught, who won for it the larger physiological interpretation of physicial training and of games, who said that the system of education must be adapted and modified for the defective child. Count up the thoughts with which these five scientific reforms have filled the heart of England, and consider what they are accomplishing in bringing "sweetness and light" into the child's schooldays, and still more into his after-days. This is a service of science "which is silently but certainly changing the prospects and hopes of the English people."

Physical Examination of School Children.

During the year under review 2,685,739 children had one examination—rather more than half the total in attendance; and besides these, no fewer than 1,719,844 re-examinations were made with the purpose of finding out whether or not the recommendations of the first examination had been carried out. There is little variation in the incidence of individual defects: defects of eyesight constitute approximately one-third of the total sum of defects, enlarged tonsils and adenoids a nearly equal proportion. The only appreciable increase has been in the incidence of enlarged tonsils and adenoids, of which the total numbers referred for treatment, both from routine and special inspections, considerably exceed those of the previous year. Such an increase does not necessarily mean any change in the physical condition of the children; it may well be due to the improved facilities for such treatment and, consequently, the greater readiness of medical officers to avail themselves of its advantages. With this exception there has been generally a very slight decrease in the numbers and proportion of children referred for treatment for most physical defects, aural defects, heart disease, tuberculosis, and deformities. There has been a perceptible decrease in the numbers of children found suffering from severe malnutrition, a decline of from 9.6 to 9.0 per 1,000 among children examined at routine inspection.

Some remarkable figures are given of the comparative findings of the examinations of groups of children in Liverpool and other cities, showing the differences between the averages for previous years and for last year. There is definite evidence of increase of height and weight. The school medical officer for London remarks: "The lessened number of children noted year by year as chronically absent from school is another proof of the improving health of the child population." This tendency towards improved nutrition and a higher standard of health appears to be general, though not universal. In London "the returns show that the children in the schools are better nourished than they have ever been before." Even in the industrially depressed areas of South Wales this tendency is felt. "The amount and nature of the evidence available," writes Dr. Jenkins of Rhondda, "justifies the opinion that if the year 1927 be taken as a whole, there has been during its course an appreciable and progressive improvement in the physical condition of the children attending the elementary schools." Dr. Pritchard of Aberdare found that, in spite of the great industrial depression, there was no increase in the numbers suffering from anaemia or malnutrition. Further, there is steady and satisfactory progress as regards personal cleanliness. The percentage of individual children found unclean in 1924 was 7.4; in 1925 it was 6.5; in 1926 it was 6.4; and for the year 1927 it was 5.6.

Provision for Treatment.

The report shows that the local education authorities are, generally speaking, fully alive to the needs of their areas. The most notable advance during the year has been the extension of provision for orthopaedic treatment. New schemes have been approved in respect of twenty-eight areas. Also new schemes for treatment by artificial light have been approved for twenty-six areas. The total number of clinics of all sorts at work last year in England and Wales numbered 1,520. Of these 936 provided treatment for minor ailments, 1,039 for dental defects, 579 for visual defects, 80 for tonsils and adenoids, 45 for the x-ray treatment of ringworm, 150 for orthopaedic defects, 26 for light treatment. The increasing popularity with parents and children of these centres is illustrated by the enormous growth of the attendances made by the children. In three Yorkshire cities the total number of attendances made at the clinics in 1914 was 123,039; in 1919 it was 323,990; and in 1927 the number was 663,305.

A new method of treatment for chronic nasal catarrh known as "diastolization" has been introduced by certain specialists in Paris, and has been subjected to trial in London and Liverpool. The essence of the treatment consists in massaging the unhealthy nasal passages by means of soft inflatable rubber bougies. It is reported that considerable improvement has resulted in the few cases that have so far been treated.

The success of ionization as a method of treatment for otorrhoea has led to its adoption by five additional authorities during the year; forty authorities now use this process. In eleven areas, 60.7 per cent. of cures are reported. Dental treatment is provided in 299 areas, an increase of five for the year; there are eighteen in which no provision has been made. It is recorded that three-fifths of the children examined and treated at each annual inspection

[1] *The Health of the School Child.* Annual Report of the Chief Medical Officer of the Board of Education for the year 1927. London: H.M. Stationery Office. 1928. Pp. 294. Price 1s. 6d. net.

are found to have some dental decay. But this fact taken by itself would create an entirely wrong impression. It is the amount and extent of decay that really matter, and these are not shown by the figures. But the figures indicate that a high proportion need some treatment year by year, and prove the necessity for continuous dental schemes. The value and efficiency of dental schemes are shown by the general improvement in the permanent dentition. In Cambridge, where there is an unusually complete dental scheme, it is found that there is a steady decline in the extraction of permanent teeth. The total worked out at one for every fourteen children examined, whereas in the country as a whole the proportion is rather more than one for every four children treated.

Artificial Light Therapy.

Approval was given during the year to schemes for treatment by artificial light in twenty-six areas; altogether forty-four authorities now have such schemes. It is evident that there is no decline in the popularity of this method of treatment, with its vivid appeal to the imagination; it is carried out at fifteen hospitals and twenty-six school clinics. Detailed reports of the results have been received from only a few medical officers. For the most part their reports have been confined to a statement of the numbers treated, with general comments on the results. This is a matter for regret. It is admittedly difficult and tedious to keep detailed and accurate records, but until this can be done on a fairly large scale, we shall not be in a position to estimate the value of the treatment for specific defects and ailments. The reports received suggest that, so far as school children are concerned, the chief benefit derived from artificial light may be attributed to tonic action. As regards any specific action on particular ailments evidence is generally conflicting and indefinite. Catarrhal cases are said to have done well in certain districts, but on the whole the evidence is negative, and this is also true in regard to nervous and choreic children. On the other hand, cases of non-pulmonary and especially glandular tuberculosis usually do well under the treatment. Broadly speaking, it may be said that this form of treatment, when undertaken by experienced practitioners, has justified itself as an adjuvant to other forms of treatment for children whose standard of health and nutrition is subnormal.

Treatment of Crippling Conditions.

New schemes for orthopaedic treatment were approved during the year in 28 areas, bringing the number of areas in which such schemes have been established up to 160. In many other areas voluntary provision, which in some cases amounts practically to a complete scheme, has been made for the treatment of cripples. Universal experience shows that the crippling conditions found among children of school age in the great majority of cases follow disabilities incurred in the period of early childhood. In Birmingham, for example, a census of cripples taken during the year revealed that 84.5 per cent. of the non-tuberculous crippling conditions arose from causes acting before school age. For this reason it is an essential of any orthopaedic scheme that there should be a system of co-operation between the various committees or authorities concerned, so as to provide for the ascertainment and treatment of cripples at the earliest possible occasion. Delay inevitably results in a prolongation of the period of treatment, with a corresponding increase in its cost; and the ultimate results are far less likely to be satisfactory.

Open-air Schools.

The view is commonly held that in open-air school work health considerations receive so much attention that education has necessarily to take a secondary place. Results from Nottingham indicate that this need not in fact be the case. It may be true that there is—as indeed there ought to be—less formal education than in the ordinary public elementary school, but any loss that might accrue on this account is more than made up for by the child's gain in brightness and general interest and pleasure in its work and play. Open-air school education requires a special technique of its own. This view was well enforced at the recent conference on open-air schools and education held in connexion with the International Child Welfare Congress at Paris. The papers read there emphasized the fact that the open-air movement is destined to have an effect, not merely in its own specialized sphere, but on methods of education generally.

(To be continued.)

EPSOM COLLEGE SANATORIUM FUND.

SECOND LIST OF CONTRIBUTIONS.

IN December, 1926, an appeal was issued by the chairman of council of Epsom College to the medical profession for financial assistance to enable the council to build a new sanatorium and isolation block, and a year later, in our issue of December 3rd, 1927 (p. 1035), we published a detailed description of the proposed building, with plans and a sketch, together with a list of donations to the new sanatorium fund.

Donations to that date amounted to almost £4,208, and subscriptions since received bring the total at the credit of the fund to just over £5,300. Until at least £15,000 is in hand it will not be possible for the council to proceed with the erection of the buildings. The second list of contributions is as follows:

£200.—St. Bartholomew's Hospital Medical Staff.

£100.—Mr. Oswald Addison and Hampstead General Hospital Honorary Medical Staff.

£79 5s. 11d.—Colonel J. Paul Bush (Stock).

£26 5s.—Mr. H. C. Highton.

£25.—Dr. E. L. Adams.

£21.—Mr. H. S. Pendlebury.

£20.—Sir William Hale-White, M.D.

£10 10s.—Dr. William A. Carden, Mr. W. Sampson Handley, and Dr. Prideaux G. Selby.

£8 15s.—Surrey Branch, British Medical Association (further donations).

£5 5s.—Mr. Andrew Cunningham, Dr. Henry J. Dunbar, Dr. C. B. Heald (*second donation*), Mr. G. J. Jenkins, F.R.C.S., Jessop Hospital (Sheffield) Medical Staff, Dr. Claude W. Morris, Mr. A. C. Palmer, and Dr. Ffrangcon Roberts.

£5.—Cambridge Medical Society, Mrs. S. M. V. Richardson, Dr. Charles Slater, and Dr. F. W. W. Smith.

£3 3s.—Dr. C. F. Peyton Baly.

£2 2s.—Brixton and Streatham Medical Book Society, Dr. E. B. Clayton, Dr. F. W. W. Griffin, Dr. R. H. Knight, Dr. T. C. Mugliston, and Dr. Frank G. Penrose.

£2.—Dr. F. M. Neild.

£1 1s.—Dr. Thomas Baker, Mrs. Theodore Bell, Dr. J. Percival Brown, Dr. E. G. Bunbury, Dr. J. A. Drake (*second donation*), Dr. Framjee Gotla, Dr. William Douglas Kirkwood, Dr. A. L. Morris, and Dr. H. A. Richards.

Victoria.

[FROM OUR OWN CORRESPONDENT.]

New Chair of Obstetrics at Melbourne.

As the result of the promise of £2,500 per annum by the Premier of Victoria, which will be supplemented by a gift of £20,000 from the Edward Wilson Trust, the council of the University of Melbourne has decided to proceed at once with the establishment of a chair of obstetrics. The council has resolved that the salary attached to this appointment shall be £2,000 per annum. The holder will not be permitted to engage in any private practice for fees while he is the occupant of the chair, and will be available, free of charge, for consultations with the medical advisers of the Women's Hospital and the Queen Victoria Hospital in confinement cases presenting features of serious difficulty or risk. Subject to these conditions the council has remitted to the faculty of medicine the task of drafting the regulations for the establishment of the chair; the faculty has not yet prepared its report.

Resignation of Professor R. J. A. Berry.

After having been associated with the University of Melbourne for nearly twenty-three years, Professor R. J. A. Berry, dean of the faculty of medicine, has tendered his resignation of the chair of anatomy to the council, and in recognition of his valuable services has

been granted six months' leave of absence, commencing in August, 1929. During his term of office as professor Professor Berry devoted himself wholeheartedly to the building up of a school of anatomy and to the teaching of students, in both of which his efforts have been most successful and much appreciated. He has also spent a great amount of time on the study of the structure and functions of the nervous system, and has embodied the results of his work in this direction in a recent publication, *Brain and Mind*. For the past several years, as dean of the faculty of medicine, his efforts have been directed particularly to forwarding the establishment of a university clinical hospital. It would have been a great source of gratification to him, and a fitting termination to his career in the city, if this had been achieved before his departure, but although this seems unlikely his work will probably bear fruit in the future. Professor Berry has many years of useful activity still ahead of him, and those who have had the privilege of being associated with him wish him every success in his future career.

Memorial to the Late Dr. R. J. Bull.

The Victorian Branch of the British Medical Association has erected a memorial tablet in the Bacteriology School of the University of Melbourne, and a statuette in the Medical Society Hall, in recognition of the valuable services rendered by the late Dr. R. J. Bull both to the University of Melbourne and to the medical profession of Victoria. Dr. Bull was director of the bacteriological laboratories of Melbourne University, and his valuable advice and kindly assistance were always willingly given to members of the profession in the state. He had a keen and original mind, and a charming personality, and but for the large amount of routine and teaching work required of him would probably have devoted more time to research. He took a lively interest in medical politics, and at the time of his death was president of the Victorian Branch of the British Medical Association. His untimely death was deeply felt by his many friends, and was a great loss to the University and the medical profession.

Future of the Veterinary School.

The report of the committee which was appointed to inquire into the future of the veterinary school has been adopted by the council of the University, and a deputation has been selected to place its recommendations before the Ministry. The committee recommended that teaching for the veterinary degree course should be continued in Melbourne up to the end of the third year, and that students should then go to Sydney for the fourth year. It was also urged that the University should continue to conduct laboratory, diagnostic, and reporting work, together with investigations of outbreaks of disease in animals, for the stock branch of the Department of Agriculture, with University officers, staff, and equipment as at present. The milk laboratory should also continue on present lines. Other recommendations were that there should be continuance of the facilities afforded to the research officers of the Commonwealth Science Industrial Research Institute up to the limits of the accommodation of the school, and an increase and extension of the endowment fund and other provisions for research work relating to matters of disease in animals by University officers. Finally, the committee proposed that a new Act be obtained providing for the above measures, and including provision for ten retainers of £1,500 per annum to veterinary practitioners located in country districts of Victoria.

Proposed Appointment of a Paid Vice-Chancellor at Melbourne University.

The council of the University of Melbourne has adopted the report of the committee appointed to consider the advisability of appointing a paid vice-chancellor. The committee has recommended that the sum of £2,000 should be provided to include salary, contribution to provident fund, and hospitality allowance, that the vice-chancellor be a full-time officer and should represent the University in dealing with outside bodies, and that he should be the chief administrative officer of the University. His tenure of office, the council decided, would be limited to a period of five years. It was decided to ask the committee to lay the proposal before the Premier and to ask for the necessary funds to carry it into effect.

Lectures by Professor F. R. Fraser.

Professor F. R. Fraser, director of the medical teaching unit at St. Bartholomew's Hospital, London, who visited Melbourne at the invitation of the Post-Graduate Committee, recently delivered a series of lectures at the Medical Society Hall. The lectures were very much appreciated and were attended by several hundred practitioners, many of whom had come from different parts of the state.

Scotland.

Maternal Mortality in Aberdeen.

A REPORT on maternal mortality in Aberdeen for the ten years 1918–27, with special reference to puerperal sepsis, has just been issued by the Scottish Board of Health, the authors being Drs. J. Parlane Kinloch, J. Smith, and J. A. Steven. In a prefatory note Dr. T. F. Dewar of the Scottish Board of Health recalls that such an inquiry was proposed by Professor Matthew Hay in 1917, prior to the suggestion of the Scottish Departmental Committee which reported on puerperal morbidity and mortality in 1924, and notes that the report falls naturally into two parts, one being a critical analysis of data collected in the ten years' investigation, and the other dealing with the essential nature and bacteriology of puerperal septic infection.

The report states that in Aberdeen the local registrars are required to forward daily to the medical officer of health a report of the deaths of women which occur during pregnancy or within four weeks after childbirth. During the ten years there were 252 puerperal deaths, but in only 219 of these was reference made to pregnancy or parturition in the death certificate, so that one in every eight of the maternal deaths was discovered by means of the special system of inquiry thus provided. It was found that of the quinquennial age periods from 15 to 49 the death rate was lowest at the period 25 to 29, amounting then to 5 per 1,000 births, while at the age period 35 to 39 the rate was doubled. A predominant part was played by sepsis and albuminuria in these maternal deaths, and the death rate from haemorrhage was found to increase steadily from 30 years onwards. The death rate among mothers of illegitimate children was found to be fully twice as great as among others. Of the 252 women concerned, 203 were engaged in household duties, 10 were fish-workers, 6 mill-workers, 13 factory workers, and the others were engaged in light employment. Alcoholism cannot be said to have played any important part as a cause of death, for the health visitors found that there was definite evidence of intemperance in the proportion of 1 in 93 of expectant and nursing mothers in general, while this occurred only in the proportion of 1 in 126 among women who died from puerperal conditions. Cleanliness of the house had a certain amount of influence, as only 92.8 per cent. of houses where puerperal deaths occurred were described by the health visitors as good, compared with 95.4 per cent. of good houses among all those visited by them. The curious fact was noted that the puerperal death rate per 1,000 births was 9.2 in houses of three or four rooms, as compared with 4.4 in one-roomed houses. The proportion of deaths from albuminuria and convulsions was definitely highest in the least crowded houses. The state of health during pregnancy had an important bearing, for the records of the health visitors showed that among all cases of births (nearly 3,000 a year) the mothers in 80 per cent. had retained satisfactory health during pregnancy, whereas among the mothers who died the health had been satisfactory during pregnancy in only 40 per cent. of cases. Only 55 per cent. of the women whose deaths were brought under review reached the normal period of gestation. With regard to the influence of syphilis, the death rate per 1,000 births among mothers of

stillborn children was eight times as great as that among mothers of live-born children, and in regard to haemorrhage it was twenty-one times as great. In Aberdeen it is the practice to have the bodies of all stillborn children who are attended by midwives and in the Maternity Hospital examined for spirochaetes, and the result showed that 12.1 per cent. of the stillbirths were due to syphilis. In respect of the danger of different confinements the second was found to be the safest, for the mortality of second confinements was about one-third that of the first confinement, while after the second the fatality again gradually increased. It was found that in the practice of midwives the death rate was 2.8 per 1,000, in the practice of doctors 6.9, and in institutions 14.9. On the other hand, the evidence showed that instrumental delivery was not associated with any increase in sepsis. Emphasis is laid upon the importance of restricting the number of patients and their spacing in maternity wards if contagion is to be reduced. The suggestion is made that infection may be brought by droplet infection of streptococci from the throats of carriers.

Bacteriological examinations were made in a series of 88 cases of puerperal fever. Examination of uterine cultures, blood cultures, and pus from secondary suppurative processes showed that in all cases the organism most frequently found was a *Streptococcus haemolyticus*. In connexion with the prevention of maternal mortality the report concludes that an important reduction would be secured by the expansion and improvement of ante-natal services. It is also suggested that such organization should be made that midwives should conduct normal deliveries, and that doctors should provide the ante-natal services and deal with obstetrical complications. For the destruction of organisms that have invaded the maternal tissues it is suggested that the production of a type (serological) specific antibacterial serum is necessary.

Edinburgh Royal Infirmary.

The annual report of the Royal Infirmary, Edinburgh, was presented to the annual meeting of the court of qualified contributors on January 7th. The report points out that on August 6th the institution will have completed 200 years of service. During the past year 19,680 patients were treated in the wards of the institution, of whom 13,176 were discharged cured, while the deaths numbered 1,084. Of the 18,792 cases admitted 4,326 were medical and 14,466 surgical. The total number treated showed an increase on that of the previous year by 957, and the average daily number of patients in the institution was 913, an increase of 10 on the previous year. The largest number of patients on any one date was 940, and the average time spent in the institution was 16.39 days, against 17.09 in the previous year. Of the cases admitted 8,815 were from Edinburgh and 9,964 from the country. The percentage of deaths in cases treated was 5.5, or deducting deaths occurring within forty-eight hours of admission, 3.8. New out-patients numbered 62,085. The total ordinary income of the Infirmary was £117,191, of which £72,749 was derived from contributions; the increase in income over that for 1927 was £5,695. Extraordinary income amounted to £49,392, of which £16,737 was carried to permanent capital. Ordinary expenditure was £136,831, against £140,539 for the preceding year, and the extraordinary expenditure was £5,849. The cost per occupied bed for the year was £149 17s. 5d., or £5 15s. 4d. less than in the preceding year, and the average cost per patient was £6 19s. 1d. According to the report, the success attending the systematic scheme of collecting small subscriptions from employees showed that this form of support was well maintained. During the year £21,435 was collected from 1,450 groups of subscribers, comprising employees engaged in public works, business establishments, staffs of schools, banks, and Government and other offices. The contributions of miners and oil workers engaged throughout the coal and shale areas served by the institution amounted to £11,141, an increase of £916. Ten tons of silver paper were collected, producing £570 for the Infirmary; it is considered that the spirit of community giving engendered by this means is well worth fostering.

Correspondence.

THE TEMPERATURE IN PULMONARY TUBERCULOSIS.

SIR,—Dr. Colin Milne contributes to your pages in the issue of December 29th, 1928 (p. 1173), a most interesting article on the temperature in pulmonary tuberculosis. There are one or two points, however, which appear to me to be somewhat ambiguous in the course of this article, or open to criticism. He states that to take the rectal temperature requires more time than other methods; yet in the next paragraph he says that with the thermometer in the mouth it is often three minutes before the mercury begins to move at all. Now in taking rectal temperatures three minutes with a minute thermometer is always long enough; whereas, as Dr. Milne indicates, and as was long ago pointed out by Dr. W. Burton-Fanning, even fifteen minutes is not always long enough to record the proper oral temperature in cold weather; and in over 70 per cent. of cases the maximum reading will not be reached after five minutes (see *Tubercle*, vol. vi, p. 179).

Dr. Milne states that an oral temperature of 99° may be considered fever. If he were more used to rectal readings I think he would be more precise and strict. He speaks frequently, too, of a normal temperature. There is no such thing as a normal temperature. The temperature varies according to the conditions under which it is taken, even when it is taken by the same method. Furthermore, as he rightly points out, one individual's normal temperature differs from another, and one sex's from that of the other. He gives interesting facts under the head of this latter point. The temperatures after resting for at least half an hour in a reclining position are the most valuable from the point of view of pulmonary tuberculosis. A further twenty years' experience confirms the conclusion which I reached many years ago and expressed in an article published in the *Lancet* in 1909 (vol. ii), that a rectal rest temperature above 98° in the morning, and above 99.3° in the evening, should be considered fever, at all events in a man. In most men, in fact, a rectal rest temperature of 98° a.m. and 99.4° p.m. will be found to be one degree higher than the average temperature of health. The temperature for oral readings should be one degree lower than this, Fahrenheit, and half a degree lower is the usual reading for urine temperatures. The presence of fever in phthisis demands rest; hence the great importance of these points.

Dr. Colin Milne speaks of a pre-menstrual rise of one week as "long." In my experience seven days' pre-menstrual rise is common, but not much less common is one which is ten days or even fourteen days.

Some references to the subject of the normal temperature will be found under the heading of "Subnormal temperatures" in the *British Medical Journal*, vol. ii, 1925; and, to the subject Dr. Milne deals with, in an article by Dr. C. G. Goodwin, published in *Tubercle*, vol. iv. He does not refer to Dr. Varrier-Jones's recent little book on *The Significance of Temperature Variations in Tuberculous Disease*.—I am, etc.,

S. VERE PEARSON.

Mundesley, Jan. 5th.

THE DEFINITION OF PUERPERAL PYREXIA.

SIR,—The standard of puerperal morbidity adopted in a recent paper in the *Journal* (December 15th, 1928, p. 1082) having been questioned by Dr. Bethel Solomons (December 22nd, p. 1155), and the matter being clearly of great importance, I have approached Dr. Alfred Cox for information regarding the "British Medical Association standard," referred to in our paper. He has kindly allowed me to publish the apposite portions of his reply as follows:

"So far back as 1905 the Council set up a Puerperal Morbidity Committee, which consisted of obstetricians from all parts of the United Kingdom. This committee met on two occasions, and issued a report of which one recommendation was that the table of puerperal morbidity should include all fatal cases and also all cases in which the temperature reaches 100° F. on any two of the bi-daily readings from the end of the first to the end of the eighth day after delivery.

"I cannot find that this report was ever submitted for the approval of the Representative Meeting, although it was reported to the Section of Obstetrics and Gynaecology in 1906. I have no doubt that it was this recommendation which was adopted, and has been referred to by some people as the B.M.A. standard of morbidity.

"In 1925, on the request of Sir George Newman, our Special Committee on the Causation of Puerperal Morbidity and Mortality considered a report issued by the Section of Obstetrics and Gynaecology of the Royal Society of Medicine. In this report appeared the following paragraph: 'For the purposes of the notification Acts and the investigations to be initiated after notification the following should be the definition of sustained puerperal pyrexia: sustained pyrexia means and includes any febrile condition occurring in a woman within twenty-one days after childbirth or miscarriage in which a temperature of 100.4° F. or higher is sustained or recurs during a period of twenty-four hours.'

"Our committee's comment on this paragraph was that the period mentioned in the second part of the paragraph should be 'more than twenty-four hours.' The Ministry of Health did not see its way to accept this suggestion of ours, and when the notification of puerperal pyrexia regulations appeared it was found that the expression 'puerperal pyrexia' was defined as meaning 'any febrile condition (other than the condition which is required to be notified as puerperal fever under the *Infectious Diseases (Notification)* Acts) occurring in a woman within twenty-one days after childbirth or miscarriage in which a temperature of 100.4° F. or more has been sustained *during a period* of twenty-four hours or has recurred during that period.'

"It is unfortunate that this confusion should have arisen, but we shall have to abide by the decision of the Puerperal Morbidity and Mortality Committee in 1925."

It appears, then, that Dr. Solomons's standard and ours conform neither with each other nor with the standard adopted by the Ministry of Health. One may deplore the lack of clarity in the language employed to give an official definition of "puerperal pyrexia" for the purpose of its notification, but it may be best, nevertheless, if all workers in this field agree to accept henceforth what seems to be intended by the Ministry's definition of "puerperal pyrexia"—that is, *a pyrexia of 100.4° F. or more affecting a woman within twenty-one days after childbirth or miscarriage, and lasting for twenty-four hours on end or occurring more than once in any given twenty-four hours.*

The actual detail of the standard seems to me to be of less importance than that it should be intelligible and unanimously accepted. I am grateful to Dr. Solomons for his criticism, but propose in subsequent studies to adopt the reading of the Ministry of Health standard which appears in (my) italics above, unless good cause can be shown to the contrary.—I am, etc.,

St. Bartholomew's Hospital, London, E.C., Jan. 2nd. RICHARD R. ARMSTRONG.

DENTAL CARIES AND VITAMIN D.

SIR,—Dr. A. E. Barnes will, I think, find sufficient evidence that the increased consumption of sugar is the chief factor in the causation in the widespread prevalence of caries if he will refer to Sir Frank Colyer's textbook on *Dental Surgery and Pathology*. Apart from the fact that "there is abundant clinical evidence to show that the use of sugar is closely connected with the amount of caries," he will be able to note that there is satisfactory statistical and other evidence leading to the same conclusion.

For the present discussion, however, it is hardly necessary even to trouble about the information he might thus derive, since Mrs. Mellanby seems to recognize that "Miller proved that the local or immediate cause of the disease was a chemico-parasitic process" (*British Dental Journal*, July 16th, 1928, p. 769). This chemico-parasitic process, as is well known, comes about from the fermentation of the sugars by bacteria, the end-product being chiefly lactic acid, which initiates caries by its action on the enamel. In view of this it seems strange that three groups of children getting from 50 to 200 per cent. more sugar than the group receiving radiostol should have been represented, as far as I can see, as being in the nature of controls.

With regard to the effect of fat in the diet, nearly thirty years ago, from clinical and other evidence, I claimed that the eating of fat was positively antagonistic to dental caries, and with regard to bacon I recently indicated that it was especially satisfactory in preventing caries, not only because it is rich in fat, but because its fibrous nature stimulates mastication, and, of course, it could not leave, indeed it actually clears away, any carbohydrate residue which might otherwise be left clinging about the teeth. As these views are somewhat widely recognized, surely care ought to have been taken by Mrs. Mellanby and Dr. Lee Pattison not to have included these foods in one group when they were not included in the other.

When highly satisfactory results are got experimentally by restricting the amount of sugar consumed and increasing the fat and detergent bacon, are we not justified in claiming it as evidence of the truth of our theory? That radiostol has nothing to do with what occurs, whether seen clinically or experimentally, is further indicated, since there appears to be little or no vitamin D in bacon fat.—I am, etc.,

London, W., Jan. 5th. J. SIM WALLACE.

CLASSIFICATION OF THE GENUS STREPTOTHRIX.

SIR,—Dr. T. Warwick Preston's article on pulmonary actinomycosis in your issue of December 29th, 1928 (p. 1172), raises an issue which is of particular interest to the bacteriologist. He describes two cases of this disease which proceeded to recovery, the diagnosis in each case being based on the demonstration of branching Gram-positive filaments in the sputum.

Assuming these organisms to have been causative of the condition, which is doubtless justifiable if they were repeatedly found predominating in fresh specimens, I wish to submit that this does not necessarily indicate a true actinomycosis. In this disease material from the lesion contains yellow granules, seen microscopically to be composed of mycelium, and culture in anaerobic media yields a characteristic growth composed of similar bodies. During the past few years I have examined material from about fifteen cases of actinomycosis of the jaw, lung, or abdomen, in which the fungus had these characters, but nearly as many others in which it departed from them. Granules may be absent; the filaments may be broken down into short lengths, easily mistaken for bacilli, or even into bodies resembling cocci, some or all may be Gram-negative; culture in anaerobic blood-broth may yield a flocculent growth instead of the solid rounded colonies of the typical *S. actinomyces*; blood is sometimes a necessary adjunct for growth, sometimes not; the rate of growth may be slow or rapid; the characteristic smell of the culture may be absent. In my experience the atypical streptothrix is more commonly found in pulmonary lesions than elsewhere; this assertion is based rather on the examination of specimens of pus from empyemata and lung abscesses than on findings in sputa. The clinical features of some of these cases differed from those of classical actinomycosis.

Although not wishing to suggest that the term actinomycosis be confined to lesions from which typical granules can be recovered, I submit there is ample evidence of the existence of more than one pathogenic streptothrix capable of causing visceral lesions in man. The prognosis, no doubt, depends on the type of organism, as may the response to various forms of treatment. The classification of the genus streptothrix as found in human disease is therefore an unsolved problem of more than academic interest.—I am, etc.,

London, W., Dec. 31st, 1928. LAWRENCE P. GARROD.

SO-CALLED "WHITE ASPHYXIA" OF THE NEWBORN.

SIR,—We were much interested in Mr. Bourne's letter of December 15th, 1928 (p. 1109), especially as it fully endorses the teaching of the past four years by Professor A. L. McIlroy in this unit.

During this period artificial respiration, hot baths, and all other mechanical forms of stimulation have been entirely

discarded in the treatment of newborn infants suffering from shock. These methods have been replaced by warmth and rest, cardiac and respiratory stimulants such as camphor and lobeline, the use of the mucous catheter, and the administration of 5 per cent. carbon dioxide + 95 per cent. oxygen by means of the apparatus devised by Professor McIlroy (*Lancet*, August 20th, 1927, p. 397).—We are, etc.,

MARGARET SALMOND,
Senior Assistant in the Unit.
BEATRICE TURNER,
Gynaecological Registrar.
Obstetrical and Gynaecological Unit, Royal Free Hospital, Gray's Inn Road, W.C., Jan. 2nd.

SIR,—In the recent correspondence on so-called "white asphyxia" of the newborn I have seen no mention of treatment by carbon dioxide inhalation.

It has been shown by repeated trials that if an infant's lungs are expanded rhythmically with a mixture of 95 per cent. oxygen and 5 per cent. carbon dioxide spontaneous respiration will be established rapidly, provided that the blood is circulating and that the respiratory centre is not hopelessly damaged.

There is little doubt that the frequent success of mouth-to-mouth insufflation (mentioned by Dr. Trumper) is due to the relatively high percentage of carbon dioxide in the operator's expired air. It is difficult to understand Mr. Aleck Bourne's assertion that in mouth-to-mouth insufflation, "nothing can happen but inflation of the stomach through the oesophagus." It is a fact that very considerable pressure can exist in the nose and mouth without any leakage into the stomach. For example, in abdominal operations, in which the stomach is in full view, I have upon several occasions increased the pressure of nitrous oxide and oxygen in the facepiece to the highest practicable point, but I have never been able to satisfy myself that any gases have passed into the stomach. Again, when performing oesophagoscopy under general anaesthesia, although the voluntary muscles are completely relaxed (as in "white asphyxia") the superior constrictor is always found to be closed, and it seems doubtful whether gases at moderate pressure would leak past it. Furthermore, if Mr. Bourne's assertion was correct, one would expect that patients upon whom intrathoracic operations were performed under differential pressure anaesthesia would suffer afterwards from abdominal distension and flatulence, but I have never heard of trouble arising from this cause.

Carbon dioxide has a much greater potency than lobeline or any other respiratory stimulant. For example, if an average man at rest inspires seven litres of air per minute, and then inhales air containing 5 per cent. carbon dioxide, he will inspire nearly thirty litres of air per minute within a few breaths. This forced breathing is of great benefit in cases of atelectasis, while a further action is a marked rise of blood pressure, which also tends to combat the shock condition of "white asphyxia."

In conclusion, I venture to suggest that if all newly born infants who showed the signs of "white asphyxia" were given carbon dioxide-oxygen inhalations without delay, their mortality rate would be considerably diminished.—I am, etc.,

C. LANGTON HEWER.
London, N.W.1, Jan. 7th.

SIR,—A mode of treatment which I have used for many years, and often with marked success, in cases of "white asphyxia" is to pass a No. 8 gum-elastic catheter into the trachea of the devitalized child.

Air should be blown into the lungs about eight times per minute. The child's head can be kept low, brandy put into the mouth, the child kept warm, and direct cardiac massage can be performed at the same time. It is quite easy, using the forefinger of the left hand as a guide, and feeling for the epiglottis, to pass the catheter into the larynx with the right hand.

After even one or two "blows," almost invariably, one feels the increased rapidity of the heart's action. When the child does make a spasmodic gasp on its own, air is drawn into the lungs free of all mucus. A soft rubber catheter can be passed, but with much more difficulty than if a gum-elastic one is used. This mode of treatment is harmless and very much more efficacious than mouth-to-mouth insufflation or other form of artificial respiration, which, as Mr. Bourne states, increases the shock.—I am, etc.,

STEPHEN SOUTHALL, M.D.
Birmingham, Jan. 1st.

SIR,—So far in this correspondence no one has suggested that there may be two types of "white asphyxia." Infants born after a difficult or prolonged labour (with or without the use of forceps) in a state of "white asphyxia" may be fairly deemed to be suffering from shock; but I would suggest that there are at least two kinds of true asphyxia in whose causation shock plays a minor part.

First, cases are not uncommon where, after the birth of the head, considerable delay occurs in the birth of the shoulders. In these cases, particularly when the cord is twisted round the neck, one sees the face go blue ("blue asphyxia"), and then, if the delay continues, the child passes, after a number of ineffective respiratory efforts, into a state of "white asphyxia." Secondly, premature inspiration resulting in the filling of the air passages with liquor amnii and blood, such as may occur in breech presentations, will produce true asphyxia. The former type is comparable with the asphyxia produced by strangulation or suffocation, and the latter with the asphyxia produced by drowning. Surely neither a drowned nor a strangled man can be said to have died of shock, but of asphyxia.

With regard to the treatment, I agree that the same measures should be adopted with the "shocked" baby as with any other person suffering from surgical shock; but, in my experience, babies who are suffering from the effects of obstructed respiration (which includes obstruction of the placental interchange of gases) respond very quickly to artificial respiration so long as the body is prevented from getting chilled. This is the type of "white asphyxia" that the midwife is most likely to be called on to treat, and a knowledge of the correct method of artificial respiration should enable her to revive most of her asphyxiated babies. From the fact that the large majority of babies so revived show no subsequent symptoms one must assume that there can be no gross lesion in the brain or meninges in most cases.—I am, etc.,

K. J. AVELING.
Watford, Herts, Jan. 6th.

SIR,—I have some forty-two years of experience in midwifery. For the past ten years I have abolished artificial respiration. I lay the baby across the bed, head hanging down and tongue out. I simply apply towels wrung out of hot water—one after the other—for a reasonable period.—I am etc.,

I. CRAWFORD.
Tredegar, Mon., Jan. 6th.

THE INTERNATIONAL CANCER CONFERENCE.

SIR,—In the course of Dr. Blair Bell's letter under this heading (January 5th, p. 42) he refers to a contribution made by me on the treatment of cancer by lead. Dr. Blair Bell makes certain statements which are so misleading as to call for correction.

With regard to the number of cases treated, twenty very carefully selected cases should be sufficient to estimate the likelihood of the method being of practical value, especially as each case was studied with great thoroughness.

To say that fifteen patients were "too ill to receive more than a very small . . . quantity of lead" is to imply that these cases were unsuitable from the beginning, and were moribund before treatment was commenced. This was not the case, as it was clearly pointed out in my paper that the patients were not moribund, and all were cases which, in the estimation of my senior colleagues, had a fair expectation of life. Every patient had to pass the very stringent clinical and laboratory tests as laid down by Dr. Blair Bell himself before being submitted to the treatment. The fact that some cases, certainly not as many as fifteen, received only a small quantity of lead was due to the grave results actually produced by the treatment.

The observation that the patients were converted into "physical wrecks" was not made only by myself, but by many of my colleagues on the committee which had charge

of the investigation. In some cases they declined to share the responsibility of continuing the treatment.

Dr. Blair Bell seems to be of the opinion that the treatment was not conducted on proper lines. I would remind him, however, that the preparation of lead used was kindly supplied by him direct from Liverpool, and that he was cognizant of the methods employed when he visited St. Bartholomew's Hospital to hear a preliminary report and to see the patients.

The treatment was conducted throughout with the greatest care, full investigations being carried out before each dose was administered. The method conformed in every detail to that laid down by *Dr. Blair Bell himself*, several members of the staff, including myself, having studied it at Liverpool.

I am still of the opinion that the treatment of cancer by lead in its present form is wholly unjustifiable, if on humanitarian grounds alone.—I am, etc.,

London, W.1, Jan. 7th. J. BASIL HUME.

POST-PARTUM ANAEMIA.

SIR,—With reference to the case of post-partum anaemia reported in your issue of December 22nd, 1928 (p. 1131), I am surprised to see no reference made by the authors to the work of Dr. Margaret Balfour of the Haffkine Institute, Bombay, on the anaemia of pregnancy and of the post-partum period.

Cases similar to that recorded are relatively common in Indian practice. One is inclined to suspect that a grave degree of anaemia was present in the last weeks of pregnancy, and that, as is usual in this disease, the profundity increased rapidly after delivery. My own experience has been that the disease, when definitely developed and under ordinary methods of treatment, is extremely fatal, either towards the end of the pregnancy or within a few weeks of delivery, and I agree that the case quoted would have inevitably terminated fatally without blood transfusion.

Two or three recent and very severe cases at St. George's Hospital, Bombay, I treated by blood transfusion, combined with liver, and these patients recovered rapidly. I give about 300–400 c.cm. of blood on three or four occasions within a week by the citration method, and I formed the opinion that the recoveries were due to the blood transfusion and not to the liver. This is fortunate in that the vegetarian Hindu will not take liver, although I understand there is now a liver extract administrable by injection which could be used.

There is no question that many cases in India go unrecognized owing to the prevalence of other profound anaemias. "Malaria" is a frequent diagnosis, owing to the invariable occurrence of fever in pregnancy anaemia. Treatment by quinine not only does not touch the fever, but actually appears to aggravate the anaemia. Compare in the present case the "influenza" from which the patient suffered before her confinement. How convenient "malaria" in the tropics and "influenza" at home to the busy practitioner for the diagnosis of unexplained fevers!—I am, etc.,

W. C. SPACKMAN, M.B., B.S.Lond.,
London, S.W., Dec. 22nd, 1928. Major I.M.S.

CARDIOSPASM OR ACHALASIA OF THE CARDIA.

SIR,—The direct questions put to me by Mr. C. C. Beatty in your issue of January 5th (p. 45) compel me to break a New Year's resolution at this early date.

1. Mr. Beatty asks me to explain the fact that the obstruction is not always at the cardia, but the answer is given in the heading of his letter, as "Cardiospasm or achalasia of the cardia" is obviously a condition of the cardia and of nothing else. I have only seen one case of the kind he mentions: in this obstruction was present in three different places, and I regarded the condition as probably one of multiple spasmodic strictures.

2. The fact that I believe in achalasia of the cardia does not make me deny the possibility of spasm of the cardia. I have seen three or four cases in which the cardiac sphincter resisted the passage of the mercury tube and gripped it after its passage, just as the anal sphincter in a state of spasm resists and grips the finger. The condition was primarily due to achalasia, but the oesophagitis caused by prolonged retention of fermenting food had led to spasm, the degeneration of Auerbach's plexus being presumably incomplete. Lavage of the dilated oesophagus resulted in the disappearance of both the oesophagitis and spasm in a few days, but the achalasia persisted until it was finally cured by the mercury tube.

3. The exact height of the residue of food in the oesophagus varies in different cases. In those which I have measured accurately it has been approximately eight inches, but no doubt the resistance of the closed cardia varies in *different individuals*.

4. The resistance of the closed sphincter is probably less in small children than in adults, owing to its slighter development, but the only measurements I have made have been in adults.

5. The sphincter does not *relax* when the column of fluid above it exceeds eight inches, as it is incapable of relaxation in achalasia; relaxation indicating an active process, the exact opposite of contraction. The sphincter is forced open, and is only kept open so long as the pressure is sufficient; its action is comparable with that of a safety valve to a boiler, which allows steam to escape when a certain pressure is reached, but closes again as soon as the pressure falls to the level at which it opens.

As Mr. G. W. Rake is at present in America I am answering the question put to him by Mr. Beatty. I find a mistake was made in copying the figures from his paper. The thickness of the wall of the oesophagus in his first specimen was 0.2 cm., 0.8 cm., and 0.45 cm. respectively at the upper end, in the middle of the hypertrophied area and just above the cardia, the measurements given in his letter being those of the diameters of the lumen.—I am, etc.,

New Lodge Clinic, Windsor Forest, Jan. 5th. ARTHUR F. HURST.

TREATMENT OF VARICOSE ULCERATION.

SIR,—In the interesting report (December 22nd, 1928, p. 1144) on the treatment of varicose ulcers, one table (No. XI) is of special interest for the following reasons. This table gives the percentage of healing in cases treated by different methods, and appears at first sight to give a guide to the relative value of various methods of treatment. It is probable that many readers will interpret it in this way, and will feel supported in doing so by the statement in your leading article on page 1147, that "the report conclusively indicates the best treatment prevailing at the present time."

However, a close inspection of the report shows that it is not justifiable to draw such conclusions from the data actually published, and I venture to suggest that if Dr. Luff is able to publish certain further data the value of the table and of the whole report would be much enhanced. The further data desired are those showing how far the cases in each group are truly comparable (of which data the duration of ulceration prior to the treatment is of most importance), and the data concerning the use of two or more methods of treatment for one case.

The duration and extent of the complaint prior to treatment are of the utmost importance in appraising the value of various methods, owing to the contrast between the ease with which the first ulcers usually heal and the difficulty which is met with in healing old ulcers surrounded by extensive areas of indurated tissue. Owing to this contrast the percentages in the table may easily be influenced by a preponderance of cases of one or other type in certain of the groups. Indeed, in the treatment by removal of veins it seems probable that a selection of especially suitable cases was made, as such selection would be most fully justified.

The desirability of indicating the conjoint use of several remedial measures is evident from the statement early in the report that 56.2 per cent. of all cases were treated with rest in bed, and 44 per cent. with bandaging. Since rest in bed alone will cure a large percentage of ulcers it is evident that the position of a method of treatment in Table XI may depend more on the extent to which the

physicians insisted on rest (or on careful bandaging) than on the value of the special treatment employed.

If such data cannot be given for all the cases they would still be of much interest for the group treated by ultra-violet light. This group shows a surprisingly high percentage of cures, especially in view of the cautions given as to the need of skilled technique and care in dosage. These warnings suggest some wider experience of cases in which ultra-violet radiation has been unsuccessful than the six cases mentioned in the report, and in the absence of details it seems possible that the high percentage of cures in this group may have been due to exceptional care or skill on the part of the physicians concerned, rather than to the specific action of the radiation.

These questions are put, not with a desire to belittle a successful piece of work, but in the hope that Dr. Luff may be able to add further weight to the evidence already given. It is also hoped that, should further collective investigations into treatment be undertaken, the need for observation and tabulation of all the pertinent variables may be yet more fully recognized.—I am, etc.,

National Institute of Medical Research, Hampstead, Jan. 7th. R. B. BOURDILLON.

CYSTICERCOSIS OF THE BRAIN.

SIR,—The case of cysticercosis of the brain described in the *Journal* of December 1st, 1928 (p. 980), recalls to my mind a very similar picture in an Indian shepherd boy who came to the *post-mortem* table in Madras Medical College some five or six years ago. The patient was admitted to the wards with a history of commencing blindness associated with fits. The true cause of his condition was obscure during life, and only revealed at the necropsy, conducted by my assistant, Dr. A. Vasudevan. The pathological description by Dr. Broughton-Alcock would equally apply to our case. The cysts were almost entirely relegated to the grey matter generally, and the optic thalamus particularly was stuffed with them. Over seventy cysts were picked from one hemisphere. These showed hooks and suckers, and were diagnosed as the bladder-worm stage of *Taenia solium*. It was somewhat curious to find a typical *Taenia saginata* in his intestine. One of the hemispheres is now to be seen in the museum of the pathology department of Madras Medical College.—I am, etc.,

W. LEONARD FORSYTH, M.B., D.P.H.,
Major I.M.S. (Ret.),
December 15th, 1928. Professor of Bacteriology, Egypt.

TONSIL AND ADENOID OPERATIONS.

SIR,—May I express my agreement with most of Mr. Herbert Tilley's letter of December 29th, 1928 (p. 1194); but, like Mr. T. A. Clarke, who writes in this week's issue, I am unable to acquiesce in the routine use of ligatures in tonsillectomy. It is most important to avoid loss of blood, and to send the patient back to bed with all haemorrhage arrested. In the majority of cases this can be achieved by the use of the "La Force haemostatic guillotine." My colleague Mr. F. C. Wrigley and myself have now used this instrument in over 500 cases, and are both enthusiastic about its value. In successful cases there is no bleeding at all, or at most a mere tingeing of the mucus, and it is unnecessary to use a single swab.

Like other guillotines, it occasionally fails, and resort must be had to dissection. I have never experienced this in children, and in only about 5 per cent. of cases in adults. We have only had one case of reactionary haemorrhage after the patient had been removed to bed. In a few cases—I do not know the exact proportion—the instrument does not arrest the haemorrhage, and then the usual methods, including possibly that of ligature, have to be adopted.

The instrument is condemned as unsurgical by Mr. Irwin Moore in his recent book *Tonsils and Adenoids*, but I have found it to produce less trauma, less post-operative discomfort, freer faucial pillars, and less cicatrization than any other. It is rather more difficult to use than other guillotines, and some practice is necessary for its efficient employment. I feel very strongly that the "La Force" guillotine should be more widely known and used in this country.—I am, etc.,

Manchester, Jan. 5th. D. LINDLEY SEWELL.

SIR,—Like your correspondent Mr. Clarke (January 5th, p. 45), I would also like to express my strong opposition to Mr. Tilley's advocacy of the routine application of ligatures in tonsillectomy.

I can truthfully affirm that I have *never* found it necessary to apply a ligature, though I have been constantly doing the operation since it was first introduced about twenty years ago. Of later years I remove *all* tonsils by the propulsive avulsive method with an abnormally blunt guillotine, and I must underline Mr. Clarke's contention that the "occasional exercise of a little patience," combined on rare occasions with the application of a pressure pad, will obviate any alarming loss of blood.

In a surgical operation the safety and efficacy of which is largely dependent upon the celerity with which it can be carried out in the average case, the elimination of every unnecessary complicating factor is highly desirable.—I am, etc.,

Cork, Jan. 7th. J. B. HORGAN.

LIPIODOL.

SIR,—In the review of our brochure on *Lipiodol in the Diagnosis of Thoracic Disease* (January 5th, p. 21) we were astonished to read the following words: "They describe the various methods of using lipiodol in chest diagnosis, favouring the crico-thyroid membrane route as 'on the whole most satisfactory,' but they omit to mention an important point in the technique, which is the incision of the skin by a scalpel before the trocar and cannula is introduced." We consider the use of a scalpel unnecessary and most undesirable, and its employment clear evidence of a faulty instrument or an imperfect technique.—We are, etc.,

F. G. CHANDLER.
London, Jan. 7th. W. BURTON WOOD.

*** Our reviewer states: "Pressure upon the trachea, especially in children, is the most frightening part of the operation for the introduction of lipiodol. A trocar sharp enough to penetrate the skin with very slight pressure is a dangerous instrument to insert into the trachea. Only by making a small incision in the skin with a scalpel can a trocar of moderate bluntness be introduced without producing discomfort."

ASTHMA RESEARCH COUNCIL.

SIR,—In view of statements which have recently appeared in the press to the effect that a "certain cure" for asthma has been found, we, the undersigned, desire to place on record that there is no such "cure" known to medical science, and that there is not any one form of treatment which is effective in all cases of asthma.

Investigations are being made under the auspices of the Asthma Research Council, and with the approval and support of the Medical Research Council and the Ministry of Health, into the mysteries of this distressing complaint which, it is hoped, will lead to a better knowledge of its origin and to the discovery of improved methods of prevention and treatment.

We hope that all interested in the subject, and especially well-to-do sufferers, will give their moral and financial support to the campaign, which will be inaugurated by the Lord Mayor of London at the Mansion House on January 15th, for a national fund to provide research centres at several of the leading London and provincial hospitals, where asthma and its allied diseases will be scientifically and exhaustively investigated. Donations and offers of assistance should be sent to Sir Albert Stern, Honorary Treasurer, Asthma Research Council, London Clinic, Ranelagh Road, London, S.W.1.—We are, etc.,

HUMPHRY ROLLESTON.
DAWSON OF PENN.
ARTHUR F. HURST.
London, Jan. 8th. F. E. FREMANTLE.

Obituary.

WILLIAM WARWICK WAGSTAFFE, O.B.E.,

M.B., B.Ch.Oxon., F.R.C.S.Eng.,
Honorary Surgeon, Radcliffe Infirmary.

THE death of Mr. William Warwick Wagstaffe in the Acland Nursing Home, Oxford, after a short illness entailing two operations, has been a painful blow to his professional colleagues and to his wide circle of friends.

Born in 1886, the son of Mr. W. W. Wagstaffe, one-time surgeon to St. Thomas's Hospital, London, "Billy" Wagstaffe was not long in showing his mettle. Starting his school life at The Beacon, Sevenoaks, he gained a scholarship at Charterhouse, and passed on to Oxford as a biological scholar of New College. While at Oxford he came under the influence of Sir William Osler, with whom he was associated in the study of the writings of Vesalius and other early anatomists. It is known that Osler held an extremely high opinion of his ability and character. Having finished his Oxford career with a first class in the Honours School of Natural Science, he entered St. Thomas's Hospital, where he soon showed that his abilities were in no way those of a mere examinee. He graduated M.B., B.Ch. in 1911, and obtained the diplomas M.R.C.S. and L.R.C.P.

After taking his medical degree he became a house-surgeon to Sir Henry Makins and Sir Cuthbert Wallace, and afterwards served as casualty officer. In 1913 he made a rapid rush to the Balkan war as a Red Cross surgeon, but had the misfortune to arrive too late for active service. He obtained the diploma F.R.C.S. in 1914. The outbreak of war in the same year found him characteristically prepared, and, as an officer of the R.A.M.C. Special Reserve, he was one of the first and most eager to respond to the call. His service in France, in which he rose to the rank of major, was marked throughout the war by a cheerful devotion to duty and an unostentatious efficiency, for which he was deservedly enrolled in the Order of the British Empire.

At the termination of the war Wagstaffe was appointed assistant to the surgical unit at St. Thomas's Hospital, where he gained first-rate experience of modern civil surgery, and thence he passed on to Oxford. He was a keen member of the British Medical Association, and served on the executive committee of the Oxford Division in 1927–28. He was married in 1916 to Margaret Cuthbertson, who was then serving as a nurse in a war hospital in the British Expeditionary Force. He is survived by his widow and two children, aged 9 and 7.

In the course of a twenty years' friendship the writer has never known "Billy" Wagstaffe anything but master of himself, content with his lot, and full of love for his fellow men. A capable athlete at half a dozen games, a lover of good books and good company, courageous and single-minded in all his dealings—while laying no claim to sainthood or genius, he was one of those completely integrated, utterly trustworthy, and lovable personalities who enrich the lives of all those with whom they come into contact. *Requiescat in pace.* A. D. G.

Dr. W. COLLIER, consulting physician to the Radcliffe Infirmary, writes:

Mr. Wagstaffe was appointed second assistant surgeon to the Radcliffe Infirmary and County Hospital in the earlier part of 1924. He had to wait but a short time for promotion, as three years later, on the retirement of Mr. Dodds Parker, he was elected honorary surgeon, with a full complement of beds. At the very outset of his Oxford career he showed his interest in all branches of surgery, attending the meetings both of the Oxford Medical Society and of the Oxford Division of the British Medical Association with the greatest regularity. At these meetings he not only took his full share in the discussions of cases and papers connected with his subject, but made several valuable surgical contributions, which added materially to the success of the meetings. This work was bringing its reward, as Mr. Wagstaffe was rapidly gaining an increasing share of the surgical work both in the city and county. The esteem in which he was held by his medical friends was amply proved by the very large number of medical men, both from the city and county, who attended his funeral. His published writings include an article (with Mr. W. W. Trotter) on "Gunshot wounds of the head," in the *Official Medical History of the War*, and a number of articles on abdominal disease from the surgical point of view, in various journals. He was secretary, treasurer, and manager of a small travelling surgical club, and its annual visits abroad helped to keep him in touch with his surgical contemporaries, and with the progress of surgery in foreign countries.

Professor ARTHUR THOMSON writes:

Directly Wagstaffe settled in Oxford (1922) he was appointed a part-time demonstrator in the department of human anatomy, and he held that post for the next six years. One likes to think that he got his love of the subject from his father, whom some senior readers will remember as not the least distinguished of the older school of "surgeon-anatomists." Be that as it may, his capacity for clear statement of facts and his careful methods of observation made him an excellent teacher for medical students, who readily appreciated his constant insistence on the practical application of what they were learning in the dissecting room. At the same time, the intimate acquaintance with the details of anatomy he thereby obtained was of the greatest advantage to him in the surgical practice which he subsequently proved himself so well fitted to undertake, and which he pursued with marked success in a career, alas! too brief. His kindness of heart and ever helpful assistance to those in difficulty made him a general favourite, and his premature death will be a source of regret to all those with whom his relations were intimate.

JAMES CHALMERS, M.D.,

Consulting Physician, Children's Hospital, and Physician, Royal Infirmary, Sunderland.

WE regret to announce that Dr. James Chalmers, who had been in practice in Sunderland for about thirty-five years, and who was well known in professional circles in the North-East of England, died suddenly at his residence there on December 31st, 1928, in his sixty-first year.

James Chalmers was born at Cummertrees, in Dumfriesshire, in 1868, and received his early education at the Wallace Hall Academy, Closeburn, pursuing his medical studies at the University of Glasgow. He graduated M.B., C.M. in 1890, proceeding M.D. in 1909. After being house-surgeon and resident physician at the Glasgow Royal Infirmary, he commenced practice in Sunderland in 1893, and in the years that followed built up an extensive connexion, giving his services freely to various institutions. He became honorary physician to the Sunderland Royal Infirmary, and, after holding a similar post at the Children's Hospital, was latterly consulting physician; in both institutions he also took an active part in the business of management. Dr. Chalmers was also intimately associated for many years with the Sunderland Orphan Asylum for Boys, as honorary surgeon and as a member of the governing body, and was honorary physician to the Parker Memorial Home. The work of the St. John Ambulance Association gained his ready support, and during the war he was commandant of a V.A.D. hospital.

In the British Medical Association he became a member of the Executive Committee of the Sunderland Division in 1912, and held various other offices later, being vice-chairman of the Division in 1920–21, and its representative in the Representative Body from 1926 until last year. In the year 1919–20 he was vice-president of the North of England Branch. He took a keen interest in the medical charities and acted as charities secretary for the Sunderland Division. He was a past-president of the North of England Glasgow University Club.

Dr. Chalmers was a deacon of the Union Congregational Church, Sunderland, where the funeral service was held on January 3rd. Among those present were many members of the medical profession and representatives of the institutions with which Dr. Chalmers was connected. He is survived by his widow, a son, and a daughter.

JAMES STEWART, F.R.C.P.Ed.

WE regret to record the death on December 2nd, 1928, of a veteran member of our profession, Dr. James Stewart, which took place at his residence in London in his eighty-ninth year. He was the son of Dr. Robert Stewart, superintendent of the Mental Hospital, Belfast. He received his education at Queen's College, Belfast, and after taking the degree of B.A. studied medicine in Dublin and Edinburgh. He took the diplomas of L.R.C.S.I. in 1864, M.R.C.P.Ed. in 1880, and F.R.C.P.Ed. in 1889. He became a surgeon in the Royal Navy in 1865, and he was serving in Jamaica at the time of the yellow fever epidemic in 1867. After leaving the service in 1870 he acted for two years as resident medical officer to the Dorset County Mental Hospital, Forston, and was senior assistant medical officer of the Kent County Mental Hospital from 1873 to 1875. In the following year he established a home for the treatment of inebriates at Clifton, Bristol, which he conducted until 1906. He was one of the original members of the Irish Medical Schools' and Graduates' Association, and was for many years its energetic provincial secretary, devoting much time and enthusiasm to the work. He was for over fifty-five years a member of the British Medical Association, was a member of the Executive Committee of the Richmond Division in 1913–15, the representative of the Lambeth Division in the Representative Body in 1921–24, and a member of the Westminster and Holborn Division, in addition to being an associate member of the Gloucestershire Branch.

DR. JAMES STEWART.

Dr. Stewart was a man of scholarly attainments, with an intimate knowledge of Greek and Latin authors, especially Homer and Horace, with apt quotations from whom it was his wont to delight his friends. A lifelong abstainer and non-smoker, he regarded his robust health as in large part due to these habits. Intensely interested in his profession and everything pertaining to it, it was his pleasure to read the *Journal* weekly, in his own phrase, "from cover to cover." Not the least of his great good qualities was his wonderful sense of humour; and his constant jokes, which were always in good taste, made him a most entertaining companion. He will be sadly missed.

Dr. Stewart was twice married, and had one son and two daughters by his first wife; he is survived by his widow. Among those present at the service at Golder's Green Crematorium on December 5th were several of his old friends and colleagues.

MR. ADAM WILSON, who died in a nursing home at Newcastle-on-Tyne on December 8th, 1928, at the age of 80, had spent the greater part of his life in that city, where he occupied a leading place among civic workers. Born in Scotland, he received his medical education at the Anderson College of Medicine, Glasgow, and obtained the diplomas L.R.C.P.Ed. and L.R.F.P.S.Glas. in 1869, being admitted F.R.C.S.Ed. in 1877. He commenced practice in Newcastle soon after qualifying, and attained a considerable degree of success. In the course of his career he was associated with many of the hospitals and allied institutions in the district, having been at one time assistant surgeon at the Walker Hospital and later surgeon to the Newcastle Dispensary and to the industrial schools. He was a keen member of the old Volunteer Force, and at the time of his retirement from it, after receiving the Volunteer Decoration, was surgeon colonel with the 2nd Volunteer Battalion Northumberland Fusiliers. In spite of the heavy claims of his professional duties Mr. Wilson found time to give his services to local public affairs. He entered the Newcastle Council in 1885, and from that time onwards took a large share in the government of the city, devoting himself particularly to the work of the sanitary committee. He was also keenly interested in educational matters and was a governor of the Royal Grammar School. In 1904 he was appointed an alderman of the city, but although he was on several occasions pressed to undertake the office of mayor the extent of his private practice prevented him from agreeing to do so. Some eighteen months ago he was made a deputy lieutenant for the county of Northumberland. Mr. Wilson was a member of the British Medical Association and a trustee of the Hospital of St. Mary the Virgin. While he identified himself intimately with Newcastle he maintained a close association with his native country and preserved contact throughout his life with many medical friends in Glasgow and Edinburgh. In his recreations also he adhered to the Scottish tradition, having been a leading member of the Newcastle Burns Club and a keen and skilful golfer.

Medico-Legal.

BOGUS DOCTOR CONVICTED.

A MAN of 50, named Robert Harry Andrews, was found guilty at Buxton Police Court on December 29th, 1928, of having on two occasions unlawfully, wilfully, and falsely pretended to be a doctor of medicine; the magistrates imposed a fine of £5 in each case, or two months' imprisonment.

The offences were committed in December, 1927, and a summons was subsequently issued, but the accused did not appear in answer to it. He was arrested at Burton-on-Trent on December 20th last. A woman witness stated that Andrews called at her house at Fairfield, Buxton, and said that he was Dr. Holloway of Tideswell, that he was travelling for the firm of Holloway, and that he gave his services free to the public every fifth year. She said she was suffering from an illness, and Andrews examined her with a stethoscope; he offered her a bottle of medicine, saying it would cure her in a month, and she paid 8s. 6d. for it. Another woman witness told of a similar call, when the prisoner asked if anyone in her house was ill, and examined her daughter, who had been ill for seven years. In this case, also, Andrews gave a bottle of medicine, and said it would cure the patient in a month. The woman paid him 2s. 6d. on account. Later, Andrews gave her husband pills to cure a cough, and subsequently called for the remainder of the money. This was refused, and information was sent to the police. A police constable stated that, in consequence of a complaint, he saw the accused, and asked him if he was a doctor. Andrews replied that he was not, but that he was a nerve specialist, admitting that he had no special qualification to act as such. In his attaché case were found a stethoscope and other instruments; the accused told the constable that he used the stethoscope to test the patients' chests to see if they could stand his treatment. It was stated that when the arrest was made Andrews was staying in Burton-on-Trent under the name of Dr. Robertson. Andrews, in his evidence, stated that he had never called himself a doctor, but had said he came "from Dr. Andrews; he never prescribed for anyone individually, or pretended in any way to be a doctor." His treatment, he said, was patented medicine, and it was not stated on the bottle that it was prepared by a doctor. He added that he had always asked his prospective patients if they were in a doctor's charge, and if so, he had told them they had better keep to the doctor.

It was stated that the accused had been previously convicted on a number of charges during the past twenty-five years, including one of embezzlement and several of obtaining money by false pretences.

Universities and Colleges.

UNIVERSITY OF LONDON.

THE following have been recognized as teachers of the University in the subjects indicated: Guy's Hospital Medical School, Dr. A. H. Douthwaite (medicine); St. George's Hospital Medical School, Dr. C. B. Levick (medicine); Middlesex Hospital Medical School, Mr. V. R. Hudson (surgery). It has been decided to institute a University Chair of Anatomy, tenable at St. Thomas's Hospital Medical School.

UNIVERSITY COLLEGE.

The following lectures will be given at University College, Gower Street, W.C.1, at 5 p.m.: Mr. G. P. Crowden, three lectures on Fatigue, on Mondays, January 14th, 21st, and 28th. Dr. A. S.

Parkes, six lectures on the Physiology of Reproduction, on Wednesdays, January 16th, 23rd, and 30th, and February 6th, 13th, and 20th. Mr. C. F. Pantin, ten lectures on Comparative Physiology, on Fridays, January 18th and 25th, February 1st, 8th, 15th, and 22nd, March 1st, 8th, 15th, and 22nd. Dr. R. J. Ludford, six lectures on Cytology in Relation to Physiological Processes, on Thursdays, January 24th and 31st, February 7th, 14th, 21st, and 28th.

The following candidates have been approved at the examination indicated:

M.P. [illegible]

R. K. Ford, M. E. MacD. Jago, Lucy Parker, H. W. Parrott. (*Branch VI, Tropical Medicine*): A. N. Kingsbury, J. N. Leitch.

UNIVERSITY OF BIRMINGHAM.

DR. R. G. MACGREGOR has been appointed lecturer in physiology.

CONJOINT BOARD IN IRELAND.

THE following candidates have been approved at the examinations indicated:

D.P.H.—A. Halpenny, R. F. G. Dickson.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—J. F. W. Leech, M. A. Walsh.

Medical News.

THE Royal Society of Medicine has arranged a joint discussion on post-operative thrombosis by the Sections of Pathology, Surgery, and Obstetrics on Friday next, January 18th, at 8 p.m. The openers will be Dr. Howel Evans, Mr. D. H. Patey, and Mr. Victor Bonney.

AMONG the courses of public lectures at University College, London, during the current term are several of some interest to members of the medical profession. On January 17th and five following Thursdays, at 5 p.m., lectures on "The chemistry of some natural drugs" will be given by Mr. H. R. Ing. A course of similar duration dealing with "The current work of the biometric and eugenics laboratories," will be given on Tuesdays, at 5.30 p.m., from January 29th to March 5th, the lecturers including Professor Karl Pearson, F.R.S., Dr. Julia Bell, and Dr. Percy Stocks. "Hygiene of the mercantile marine" is the subject of three lectures to be delivered by Dr. J. Howard Jones, medical officer of health, Newport, on Fridays, February 22nd, March 1st and 8th, at 5.30 p.m. Dr. J. H. Burn, director of the laboratory of the Pharmaceutical Society, will be the lecturer at three illustrated lectures on "The properties of, and methods of estimating, some therapeutic agents," at 5 p.m., on Wednesday, Thursday, and Friday, February 27th, 28th, and March 1st. On Thursday, February 14th, at 6 p.m., Professor P. Abercrombie will speak on "Town planning in town and country"; and on the following evening, at 5.30 p.m., Mr. Geoffrey Peto, M.P., will discuss "The Local Government reform scheme and de-rating." Dr. A. Maitland Ramsay will give three lectures in the Medical School on "The eye in general medicine," with lantern illustrations, on March 4th, 6th, and 8th, at 5.30 p.m. These lectures will be given at the College, Gower Street, W.C.1, admission being open to all without fee or ticket.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that on Wednesday, January 16th, at 4.30 p.m., the new series of demonstrations arranged at the Wellcome Museum of Medical Science, 33, Gordon Street, W.C., will begin, when Dr. Helen Mackay will speak on some recent work in connexion with rickets. There is no fee for this demonstration. The new series of lectures entitled "Pitfalls in medicine and surgery" will start on Monday, January 21st, at 5 o'clock, at the London Medical Society, 11, Chandos Street, Cavendish Square; Dr. Robert Hutchison is the first lecturer, his subject being "Pitfalls in the diagnosis of dyspepsia." A lecture, for which there is no fee, will be given on Thursday, February 14th, at 4.30 p.m., at the Medical Society, by Dr. Gerald Slot, on calcium therapy. An intensive course in cardiology at the National Hospital for Diseases of the Heart, and an all-day course at the Queen's Hospital for Children, begin on January 14th, continuing for a fortnight. From January 28th to February 9th an intensive course in medicine, surgery, and the specialties will be given by the staff of the Prince of Wales's General Hospital, Tottenham. *On Tuesdays and Saturdays, at 11 a.m.*, from January 29th to February 23rd, a series of lecture-demonstrations in psychological medicine will be given at the Bethlem Royal Hospital by Dr. Porter Phillips and his staff. Copies of the syllabuses and information regarding the general course of the Fellowship of Medicine will be forwarded on application, as also copies of the *Post-Graduate Medical Journal*. Weekly demonstrations in medicine and surgery, to which admission is free, will be resumed shortly. A full list covering the next three months, may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

THE first of a series of special post-graduate courses at the Royal Northern Hospital begins on Monday, January 28th, when the opening lecture in a course on gastro-enterology will be given at 2.30 p.m. In all, the course will comprise fourteen lectures covering the subject in its medical, surgical, radiological, and pathological aspects. Applications for admission to the course, which is intended primarily for those engaged in general practice, should be accompanied by the fee of £2 2s., and should reach the secretary of the hospital, Holloway, N.7, not later than January 21st. Further particulars and information relating to other special courses to be held during the year may be obtained from the dean at the above address.

A COURSE of advanced lectures on infant care in preparation for the crèche nurses' advanced certificate granted by the National Association for the Prevention of Infant Mortality and the National Society of Day Nurseries will be given, under the auspices of these bodies, by Dr. Victoria Bennett at Carnegie House, 117, Piccadilly, W.1, on Thursdays from January 17th to March 21st at 7.30 p.m., followed by an examination on Saturday, March 23rd, at 2.30 p.m. Full particulars may be obtained from Miss Maddocks, secretary, National Society of Day Nurseries, at the above address.

THE People's League of Health announces that the ninth annual series of Sims Woodhead Constructive Educational Health Lectures will be given at the Medical Society of London, 11, Chandos Street, London, W., on Fridays, from January 18th to March 22nd, and on April 12th and 19th, in each case at 6 p.m. The first lecture, on "The need for a national stocktaking," will be given by Mr. C. J. Bond; most of the others are also by medical men, the series forming a connected study on the physiology and care of the body and mind. There will be an optional examination at the close of the course for those who have attended the series; certificates will be issued by the medical council of the League, and it is proposed to award a travelling scholarship enabling a visit to be made to a foreign country with facilities for seeing its health centres. The fee for the series is 12s.; tickets and further particulars may be obtained from the general secretary of the league, 12, Stratford Place, W.1.

THE annual meeting of the Royal Microscopical Society will be held in the Lecture Hall at 20, Hanover Square, W., on Wednesday, January 16th, at 8 p.m., when Mr. Joseph E. Barnard, F.R.S., will deliver the presidential address on "Some aspects of ultra-violet microscopy." The Biological Section will meet in the Library on Wednesday, February 6th.

A JOINT meeting of the Medico-Legal Society and the Maternity and Child Welfare Group of the Society of Medical Officers of Health will be held on Thursday, January 24th, at 8.30 p.m., at 11, Chandos Street, W.1. Sir William Willcox, president of the Medico-Legal Society, will take the chair, the subject for discussion being: "Criminal abortion and measures necessary to restrict the sale of abortifacient drugs." The speakers will include Sir Bernard Spilsbury, Professor Beckwith Whitehouse, Mr. H. D. Roome, Dr. F. J. McCann, and Dr. R. A. Lyster. Members, on producing their private cards, may introduce guests to the meeting. An invitation to be present is extended to all members of the Society of Medical Officers of Health, particularly those of the Metropolitan and Home Counties Group. Representatives of the press, other than medical and legal journals, will not be admitted to the meeting.

MESSRS. J. and A. CHURCHILL announce for early publication: *Surgery in the Tropics*, by Sir Frank Connor; *The Radium Treatment of Cancer*, by Mr. Stanford Cade; and *Surgical Radiology*, by Mr. A. P. Bertwistle. Also two new volumes in the recent advances series: *Psychiatry*, by Dr. Henry Devine; and *Cardiology*, by Drs. C. F. T. East and C. W. B. Bain.

WE have received a bound copy of the sale catalogue of *Early Books on Medicine, Natural Sciences and Alchemy*, published by L'Art Ancien S.A. of Zürich. The work, the first three parts of which were issued separately at Lugano, and were noticed in previous issues of the *Journal*, contains scientific and bibliographical descriptions of 1,988 books published between 1463 and 1800, illustrated by contemporary woodcuts. A subject index is appended.

THE January number of *Leprosy Notes* contains the first section of a series of notes on leprosy in European countries, attention being devoted in the first place to those bordering the Baltic Sea. Dr. Henry Fowler contributes a brief sketch of the extent and general conditions of leprosy in China, and Dr. H. C. de Souza-Araujo discusses its incidence in Brazil. Leprosy work in British Guiana is described by Dr. F. G. Rose, and several short therapeutical articles make up the bulk of an interesting issue.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (*telegrams: Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

WANTED—A HOME.

"X." would be glad to hear of an institution where a recent case of paraplegia would be received for treatment. The patient, a retired medical man (of small means), has had considerable naval and military service.

CHROME ULCERATION.

DR. J. S. GRIFFITHS (Eaglescliffe, Durham) asks for information how to treat chrome sores and the ulceration of the nasal septum which occurs in workers with chromic acid in the manufacture of bichromate of potash. He states that these sores are most persistent, and, although painless, burrow deep down and become septic, rather assuming the appearance of the perforating ulcers which occur in diabetics.

TREATMENT OF MEMBRANOUS COLITIS.

DR. J. CURTIS WEBB (Cheltenham) writes: In reply to the inquiry of "A Country Doctor" (December 29th, 1928, p. 1202), I would like to urge him to try ionization of zinc sulphate by means of enemata, a method which I described in the *Lancet* (April 22nd, 1911). If "A Country Doctor" would care to communicate direct with me I should be very glad to give him all information of a treatment which I and others have found most satisfactory.

INCOME TAX.

Cash Basis.

"J. M." was in a partnership which was dissolved as from May 1st, 1927. He has been assessed for 1927–28 on the amount of the receipts earned prior to May 1st, 1927, which came to hand after that date, and also on the earnings for the eleven months to April, 1928, whether received or not.

*** The assessor is correct in declining to apply the cash basis to the new practice for the period subsequent to the date of dissolution of the partnership, but we are clearly of opinion that his method of dealing with the cash received for prior work is wrong and is unfair to our correspondent. So far as that work is concerned, "J. M.'s" only liability is to bear his share of an assessment on the partnership for the period April 5th to May 1st, 1927. That assessment should be calculated at 25/365ths of what would have been the amount of the assessment on the firm for 1927–28 if the partnership had not been dissolved. We suggest that "J. M." should press for a reply to his letter to the assessor, and in the absence of a proper revision of the assessments should place the facts before the Controller of Inland Revenue, Edinburgh.

LETTERS, NOTES, ETC.

SUDDEN DEATH IN UNRECOGNIZED SCARLET FEVER.

DR. F. STANLEY ROSE (Sunderland) writes: I was called in September, 1928, to see a boy, aged 3½, at a farmhouse, who had been taken suddenly ill with vomiting and diarrhoea. It was stated that he had been quite well up to a few hours previously, except that he complained of thirst. On arrival, within an hour, I found he had died. I could glean no facts which would enable me to formulate a cause of death. Two days later, at the necropsy, I was struck by the pallor of the omentum, stomach, and intestines. The stomach contained some pale yellow, odourless fluid: I thought of poisoning, as at that period of the year children often eat tares and such-like. The gall-bladder was tightly distended with green bile, but the liver seemed normal. Both kidneys were slightly congested; the appendix was eight inches long and trailed over the pelvic brim. The spleen was enormously enlarged, soft, and friable. Remnants of the thymus were prominent. The heart musculature was firm, but the valves showed early endocarditis; there was some excess of fluid in the pericardial sac, and its lining was dull. The right lung was normal, but in the upper lobe of the left lung there was a marked and well-defined infarction on the antero-lateral surface. After completing the examination I was called to see a sister (twin) and found her suffering from scarlet fever: another of the same family later developed it. I am of opinion that the boy must have had scarlet fever and been running about with it on him. The interesting point is the large size of the spleen. These odd cases are always worthy of record. I found that the boy's home was partly a dairy farm, but no worker complained of sickness or otherwise, and the cows were reported healthy.

TREATMENT OF CHRONIC RHEUMATISM IN MALARIAL PATIENTS.

LIEUT.-COLONEL G. H. YOUNGE, R.A.M.C.(ret.), F.R.C.S.I., writes: Relapses of malaria, which occur among returned Anglo-Indians during the cold and damp of winter, are not infrequently complicated by trying forms of muscular rheumatism, affecting chiefly the muscles of the back and lower extremities. A feature of these cases is that quinine frequently loses its efficacy, and in some cases may even aggravate the patient's suffering. Recently in these cases I have been led to try what is to me a new combination; I have found it distinctly more beneficial than preparations of quinine. The prescription is as follows: Sodium salicylate gr. xx, potassium bromide gr. x, tincture of cinnamon ℥j, water to ℥j; three times a day. This combination is especially indicated when insomnia is a feature of the case. The addition of cinnamon is a distinct improvement, since it not only masks the nauseous flavour of the salicylate, but it has a remedial action against the malarial poison. The patients often need a moderate allowance of alcoholic stimulant.

PAINFUL SHOULDER.

DR. F. G. BUSHNELL (Plymouth), with reference to Mr. P. B. Roth's letter on traumatic synovitis of the shoulder-joint, published in our issue of December 22nd, 1928 (p. 1156), writes: I have had a similar personal experience of a painful left shoulder following a heavy fall. I had limitation of movement, pain spontaneous and worse on movement, tender spots on pressure at the insertion of the deltoid and at the outer end of the infra-clavicular fossa, and some muscular wasting of the shoulder. The condition was treated as "fibrositis," though in the skiagram a well-known Swiss orthopaedic surgeon pointed out some rather doubtful rarefaction of the cancellous tissue, possibly of traumatic origin. Six months' treatment by massage, movements, radiant heat, etc., gave little or no relief, but all symptoms disappeared during the summer months when I took some sun baths, and the massage and forced movements were omitted. If rest can relieve such a case in two or three weeks, and movements, etc., fail in six months, Mr. Roth's warning is very timely.

THE HISTORY OF CINCHONA.

"B." writes with reference to the article by Mr. C. J. S. Thompson on cinchona (December 29th, 1928, p. 1188): In *Blackwood's Magazine* for May, 1927, there is an article on "The savage as scientist," in which the treatment of general paralysis of the insane by malarial infection, and the cure of the malaria by "bitter herbs," is described. I would like to ask if the "bitter herbs" there mentioned were probably plants containing some of the cinchona bases? If this were so, would it not show an earlier use of the bark as a cure for malaria than that mentioned in the article?

ASTHMA RESEARCH.

IN our reference to the work of the Asthma Research Council on January 5th (p. 29) it should have been mentioned that the clinic in course of establishment at the Hospital for Sick Children, Great Ormond Street, will be under the joint direction of Dr. E. A. Cockayne and Dr. D. N. Nabarro.

CORRIGENDA.

DR. H. MARTIN GREY calls attention to a clerical error in his note on "A Normal Ventriculogram," published in the *Journal* of January 5th (p. 15). The words "of the pupils," in the fourth line of the small print, should be omitted.

WE are asked to state that Dr. Ninian Falkiner was recently appointed visiting gynaecologist to the Royal City of Dublin Hospital and not to the Coombe Hospital, as mentioned in the *Journal* of January 5th (p. 38).

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 44, 45, 46, 50, 51, and 52 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 48 and 49.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 15.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

34. Medico-Legal Aspects of Suprarenal Insufficiency.

P. MAZEL and A. COSTEDOAT (*Journ. de Méd. de Lyon*, November 20th, 1928, p. 659), who record an illustrative case, state that the forms of suprarenal insufficiency which are interesting from the medico-legal standpoint may be divided into two groups: (1) the fulminating forms causing sudden death; and (2) acute forms in which death occurs in a few hours or days with gastro-intestinal signs and abdominal pain resembling acute intoxication which may therefore suggest criminal poisoning. The causal lesions may be of a tuberculous or haemorrhagic nature. In the last case they are frequently accompanied by cutaneous manifestation in the form of purpura, and are found in the adult or child, their occurrence in the latter being favoured by the frequency of infections and gastro-intestinal intoxications as well as by excessive functional activity of the suprarenal glands at that age. There is no necessary relation between the haemorrhagic or caseous nature of the lesions and the clinical course. Sudden death appears to be most frequent in apoplexy of the suprarenals, but it is also found in tuberculosis of these organs. Acute or fulminating suprarenal insufficiency may sometimes follow an accidental trauma, surgical operation, or delivery. The authors remark that a knowledge of these facts is essential for the medical jurist, and necessitates a systematic examination of the suprarenals which is frequently neglected in the performance of a necropsy. The authors' patient was a labourer, aged 38, who died after three days' illness with acute abdominal symptoms suggesting an intoxication. The necropsy showed caseation of both suprarenals with numerous tubercles in the right gland. Subsequent inquiry revealed the fact that the patient had suffered from increasing asthenia for the previous three years.

35. Therapeutic Meningitis.

S. KATSENELBOGEN (*Rev. Méd. de la Suisse Romande*, November, 1928, p. 967) remarks that the intraspinal route, which was first reserved for injection of serums and afterwards for anaesthetics as well, is now employed for the introduction of all kinds of drugs. As a general rule, more or less marked meningeal reactions follow an intraspinal injection, whatever drug is employed. The author records fifteen cases in which the symptoms followed injection of various doses of casein which were given at intervals of two to four weeks for the treatment of tabes, the sequels of epidemic encephalitis, and disseminated sclerosis. The symptoms usually first appeared five to six hours after injection and reached their height in eight to twenty-four hours; they then gradually disappeared in the course of three or four days. The intensity of the meningeal symptoms did not always have a direct relation to the dose of casein injected. On the other hand, intense clinical symptoms were always accompanied by well-marked reaction in the cerebro-spinal fluid, which consisted in a very pronounced leucocytosis in every case, but not invariably in a considerable increase of albumin. The author recommends that in giving intraspinal injections of any drugs it is always advisable to start with a very small dose in order to determine the sensitiveness of the meninges.

36. Diagnosis of Tuberculosis by Duodenal Intubation.

J. DE PALACIOS G. CORTINA (*La Med. Ibera*, November 17th, 1928, p. 469), who records ten illustrative cases in patients aged from 16 to 37, emphasizes the importance of examining the duodenal fluid removed by Einhorn's tube in cases of latent pulmonary tuberculosis. In two of the ten cases the sputum had at one time contained tubercle bacilli, and of the remaining eight patients one had had no sputum, and examinations of the others had always yielded negative results. While direct examination of the bile showed tubercle bacilli in only two cases, inoculation of guinea-pigs gave a positive result in all but one. The author concludes that the method is of considerable value in doubtful cases, while the technique is relatively simple.

37. The Functional Factor in Thyroid Diseases.

B. BREITNER (*Wien. klin. Woch.*, November 15th, 1928, p. 1592) emphasizes the importance of the advance made by modern research in defining the function of the thyroid gland in health and the modifications which occur in various types of pathological conditions. The use of iodine in goitrous manifestations, hitherto empirical, has now been placed on a scientific basis, and the indications for its effective employment have been definitely established. Not only does success in the treatment of thyroid disease depend on these underlying functional factors being kept in mind, but it is in this way alone that effective prophylaxis can be secured. Pathological changes in many cases are found to have a functional origin which requires attention. Surgical procedures are, however, still necessary on occasion: indeed, the discovery of the importance of functional factors has led to a fuller knowledge of the way in which operations bring about their good results in suitable cases.

38. Herpes Zoster and Varicella.

H. ALTERTHUM (*Monatsschr. f. Kinderheilk.*, October, 1928, p. 330) reports that in the course of eight years 36 cases of herpes zoster occurred in a children's institute at Berlin, 23 of which were undoubtedly connected with varicella, while the remaining 13 had no such connexion. The majority of varicella cases therefore were of varicellar origin. The number of cases of varicellar zoster did not run parallel with the incidence of varicella in the institute, but there was a rather striking outbreak of herpes zoster of varicellar origin in certain years. Seven cases of zoster following treatment by neosalvarsan or bismuth were observed, and 6 of these cases were undoubtedly connected with subsequent attacks of varicella. These observations, therefore, are in favour of the view that arsenical zoster may be of varicellar origin. An attack of varicella does not confer immunity against herpes zoster or vice versa. The practical conclusion to be drawn from these observations is that if an institute is to be kept free from chicken-pox every case of zoster should be at once isolated, and the ward in which it occurs should be placed in quarantine.

39. Paratyphoid B Infection with Purpura and Broncho-pneumonia.

H. P. JAMESON and A. SIGNY (*Arch. Dis. Child.*, October, 1928, p. 238) record a fatal case in a girl, aged 8, who during convalescence from paratyphoid B infection developed purpuric patches in the skin, subconjunctival haemorrhages, haematuria, and haematemesis. Death ensued about ten days after the first appearance of purpura; the necropsy showed suppurating pneumonia almost confined to the upper lobe of the right lung, punctate haemorrhages all over the pleurae, pericardium, brain, and intestines, and an extensive subperitoneal haemorrhage in the left iliac fossa. *B. paratyphosus* B was recovered from the lungs and mediastinal glands. There was an almost complete absence of any intestinal lesions.

Surgery.

40. The Sesamoid Bones in Hallux Valgus.

H. TIMMER (*Deut. med. Woch.*, November 16th, 1928, p. 1927) has studied the anatomy of hallux valgus in a number of necropsy cases and by *x* rays, and states that the shape and position of the sesamoid bones, which can be recognized in radiograms, is of considerable importance in the diagnosis and treatment of this condition. In mild cases the lateral sesamoid still lies partly under the head of the first metatarsal; in more severe cases it is displaced under the interosseous space; and in the worst cases both sesamoids lie laterally to the first metatarsal. Though the short plantar muscles of the great toe are attached to one or both sesamoids before their insertion into the first phalanx, and the tendon of flexor longus hallucis lies between them, it was found that the actual displacement of the sesamoids, and therefore of these muscles, was always less than seemed probable from the clinical picture. In shape the sesamoids are normally spherical in their lower part, and covered with saddle-shaped cartilage on the articular surface. If the lateral sesamoid is displaced to the lateral side of the head of the first metatarsal, and is semilunar in shape, it indicates that considerable contraction of the lateral part of the corresponding metatarso-phalangeal joint has occurred. If treatment is to be successful an attempt must be made to rectify this, and the flexor and abductor tendons of the toe must also be made to return to their normal position; evidence of this can best be obtained from an *x*-ray examination of the position of the sesamoids to which they are closely related.

41. Collapse Treatment of Pulmonary Tuberculosis.

J. GRAVESEN (*Ugeskrift for Laeger*, November 29th, 1928, p. 1111) reports the following statistics from Vejlefjord Sanatorium, Denmark. There were 77 patients on whom thoracoscopy and cauterization of pleural adhesions were attempted, and 54 on whom these procedures could be completed; 5 of these patients were still undergoing treatment at the time of the report. Of the remaining 49, as many as 20 were discharged as much improved, and 23 as improved. Tubercle bacilli had been found in the sputum of all 49 patients, and could no longer be found in 20 patients on discharge. Of the 41 patients who had been thus operated on two to ten years earlier, as many as 17 were found to be fully fit for work, and 5 partially fit. Five still suffered from their tuberculosis, and 14 had died from it. Among the 182 patients on whom thoracoplastic operations were performed, there were 13 whose deaths were caused or hastened by the operation. Thus, there was an operation mortality of 7.1 per cent. The first 9 operation deaths occurred among the first 100 patients, whereas the operation mortality for the last 82 patients was much reduced. This reduction was traced to improvements of the technique and the employment of preliminary partial operations. Of the 182 patients, 8 were still undergoing treatment. Of the remaining 174, as many as 41 were discharged as much improved, 78 as improved, 2 as unimproved, and 21 as worse. The remaining 32 patients died in the sanatorium. Tubercle bacilli were found in the sputum of all these 174 patients, and 62 of them were sputum-negative on discharge. To ascertain what the permanent results were the author analysed the fate of the 155 patients whose operations dated back two to twelve years. He found that 37 were fit for ordinary work and 28 for light work. Eight still suffered from tuberculosis, 74 had died from it, 4 had died from some other disease, and the fate of the remaining 4 was unknown. As many as 52 of the survivors were sputum-negative. Thus, in a class of case in which only 10 or 15 per cent. of the patients can expect to achieve fitness for work as a result of conservative treatment, thoracoplastic operations brought up the percentage to 42.

42. Complete Inversion of the Viscera.

G. GANELLI (*La Pediatria*, November 15th, 1928, p. 1220) reports a case of complete inversion of the viscera. A boy, aged 6, was admitted into hospital for broncho-pneumonia, and on examination was found to have the heart on the right side, the liver on the left, and the spleen and stomach on the right; by means of a barium enema the sigmoid was shown to be on the left side. There was a double mitral lesion, but apart from this and the bronchial attack the boy was healthy. When 2 years old he had a slight attack of anterior poliomyelitis affecting the right forearm, from which he had practically recovered; otherwise he had had no illness. The family history was good, and there was nothing to suggest why this child should be so affected. The author discusses the various theories which have been put forward to explain these cases, but does not find any of them applicable to his case. There was no evidence of left-handedness in the boy, and apparently the inversion of the viscera did not in any way affect his health.

43. Thorn Wounds.

IN view of the statement that the thorns of certain trees are peculiarly poisonous UTEAU and BOUGET (*Bull. et Mem. Soc. Chir. de Paris*, November 2nd, 1928, p. 715) made a careful inquiry in one particular case and found the fact of virulence established in so far as the particular bush was concerned. The cause, however, did not lie in the thorn, but in the nature of the material with which it was soiled. This consisted of the decaying remains of various forms of small animal life (mice, insects, birds, etc.) impaled on the thorns by a bird of prey (a shrike) which used this bush as a sort of larder for food which it could not immediately make use of. When the thorns were properly cleansed they did not cause infected wounds.

44. Trauma and Carcinoma.

J. M. WAINWRIGHT (*Amer. Journ. Surg.*, November, 1928, p. 433) reports three definite cases to prove that a single trauma can cause carcinoma or sarcoma, but he admits that such cases are rare. In each instance the trauma was of sufficient severity to devitalize or alter considerably normal tissues. Wainwright considers that the trauma must also be sufficient to cause definite pain, swelling, ecchymosis, and more or less impairment of function—that is, conditions which leave some real scar tissue. The time between the injury and the tumour symptoms varies: in one instance it was eight weeks, in another seven months, and in the third two years. Cases have also been known of carcinoma developing in the scar of a burn as long as thirty-five years after the burn had healed, and a case is reported of a man, aged 74, in whom a malignant growth developed in the scar of a foot amputation operation performed in childhood. Carcinoma in the male breast is frequently due to blows, gunshot wounds of the nipple, or the continued pressure of tools as used by carpenters or shoemakers. Again, the constant irritation of the skin, particularly of the scrotum, by the oil with which a mule-spinner in the cotton industry is continuously in contact, causes mule-spinner's cancer. A severe trauma of any kind applied directly to a carcinoma may aggravate it and make it grow more rapidly.

Therapeutics.

45. Treatment of Psoriasis.

BURNIER and LOTTE (*Journ. de Derm. et Syph.*, July, 1928, p. 625) record results of treating 58 patients with a compound of bismuth, arsenic, and pyridine, introduced by Debucquet, Jausion, and Pecker under the name of psothanol. They gave intravenous injections three times weekly up to an average total of 20 doses. In general, though not always, recent lesions were found to clear up quicker than those of long standing, the thicker and more squamous plaques being least responsive. In favourable cases the plaques disappeared, first at the centre and last at the periphery, cure being complete after three to twenty injections. Total disappearance of lesions resulted in 21 per cent., and great improvement in 44 per cent., the scales and discoloration remaining only at the periphery of the lesions. Slight improvement occurred in 23 per cent., the scales becoming less numerous and thick, though still present over the whole area of the lesions. In 10 per cent. of the cases there was complete failure. Recurrences appeared in six cases, of which only one yielded entirely to a further course of treatment. New lesions developed during the course of treatment in six cases. Mild complications, such as slight rises of temperature, headache, toothache, stomatitis, albuminuria, vertigo, articular pains, occasional pruritus, but never erythrodermia, were noted in ten cases. Intolerance, shown by marked stomatitis, bad articular pains, and albuminuria, was manifested in two cases. The authors conclude by remarking that, though the drug is not always efficacious, the results with it are more constant, and the treatment less dangerous, than is the case with gold salts. They describe two cases of the articular variety where treatment resulted in the freeing of contracted joints, and enabled previously bedridden patients to resume a certain degree of activity.

46. Reduction of Cerebral Hypertension.

As the result of clinical and experimental investigation RISER and R. SOREL (*Paris Méd.*, December 1st, 1928, p. 475) conclude that for the reduction of cerebral hypertension the most appropriate procedure is the intravenous injection of 100 c.cm. of a 50 per cent. glucose solution in serum, raised to body heat, the injection being spread over five minutes. If sodium chloride is used, the amount given should not exceed 0.25 gram of dried salt per kilogram of body weight in a 10 per cent. solution. The authors find that the administration of salt, though more constant in its effects, is much less safe, and unpleasant sequels may occur. Injections of glucose are said to be indicated in such transitory hypertensive conditions as follow lumbar puncture; in severe headache due to serous meningitis in the course of infections; in certain traumatic, but transitory, hypertensions; and, above all, in medical haemorrhagic meningitis, which is nearly always accompanied by headache and cerebral hypertension, and must not be treated by lumbar puncture. The authors believe that such hypertonic injections are also very valuable in cases of tumour of the brain before or during an operation.

47. Antipyretics in Pulmonary Tuberculosis.

E. GARCIA DEL REAL, jun. (*Ibera Medica*, December 8th, 1928, p. 565), states that in cases of ambulatory fever in pulmonary tuberculosis it has to be decided whether the fever is directly due or not to pulmonary tuberculosis. In the former case the symptoms yield readily to a rest cure, while in the latter this has hardly any effect, and benefit may be obtained by opium preparations, especially in some forms of juvenile phthisis. Occasionally, and especially in private practice, it is necessary to resort to antipyretics, one of the most useful of which is pyramidon, given in powder or solution in doses of 15 to 30 cg. Gardan, which is a combination of pyramidon and novalgin, has recently been advocated, since, unlike pyramidon, aspirin, and other antipyretic drugs, it causes a fall of temperature without sweating. The dose is half or one tablet three-quarters of an hour before the usual rise of temperature.

48. Treatment of Epidemic Meningitis by Antibody Preparations.

J. B. NEAL, H. W. JACKSON, E. APPELBAUM, and E. J. BANZHAF (*Journ. Amer. Med. Assoc.*, November 10th, 1928, p. 1427) state that in view of the unsatisfactory results from the use of ordinary antimeningococcal serum an antibody preparation was made from it. The results were generally favourable, the mortality among the first twenty-four cases treated by it being only 12.5 per cent. Of the three fatal cases, one patient had been ill six weeks before the meningitis was recognized, one died during a relapse which had been present more than a week, and the third patient developed severe meningeal haemorrhage and died as the result of it. Of the patients who recovered from the meningitis, two died within a few weeks, one from streptococcal septicaemia and the other from pneumonia, but in both instances all clinical and spinal fluid evidence of meningitis had disappeared. Some of the patients were treated with the antibody from the first, and responded with unusual promptness; in other cases the antibody was used after the ordinary serum had failed to produce results.

49. Intravenous Injection of Hexamine in Pleurisy.

DR. J. GAZÁREK (*Bratislavské Lekarské Listy*, November, 1928, p. 601) reports the obtaining of very good results in pleurisy with effusion by administering intravenous injections of hexamine. There was a rapid fall of the temperature to the normal in ten to fifteen days and a relatively quick absorption of the effusion. The treatment, which is said to be simple and harmless, prevented also recurrence of the exudation after withdrawal of the fluid by puncture. Recent cases of so-called idiopathic pleurisy respond particularly well, but the results were less favourable in symptomatic pleurisy in tuberculosis or syphilis. The author adds that this procedure has hardly any influence on possible sequels of pleurisy, such as formation of adhesions.

Radiology.

50. Radiotherapy in Angina Pectoris.

C. LIAN and M. MARCHAL (*Paris Méd.*, December 1st, 1928, p. 465) strongly advocate *x*-ray irradiation in cases of angina pectoris, especially when medical measures have proved of no avail. Lian previously formulated a wider definition of this disease than that usually held, and concluded that it might complicate any myocardial or pericardial valvular condition, and might also be a sequel of certain digestive affections, biliary lithiasis, intoxications, and neuropathic states; in fact, he considered that angina pectoris was present in all paroxysmal pain of the sternal or precordial region with left brachial irradiation, and anguish (thoracic constriction and sensation of impending death). The present authors state that angina pectoris is due to a vaso-constrictor or pressure reflex, which, caused by an excitation of the cardiac plexus, sharply aggravates the cardiac disturbance, of which pain is the clinical expression. They have found that great and usually lasting benefit follows *x*-ray treatment in angina pectoris, and that the danger of its causing cardiac insufficiency or increased pain is negligible. Improvement usually commences during the second week of treatment, and gradually increases. Weak irradiation is advised, since strong doses are liable to cause exacerbations and to delay improvement, but the irradiations must be frequent (three a week). They employ a spark equivalent of 25 cm., a 6 mm. aluminium filter, an intensity of 2.5 milliamperes, and a skin-anticathode distance of 30 cm. Two fields are irradiated: a precordial one of 20 cm. diameter over the internal part of the third left intercostal space, and a dorsal one of the same diameter over the third dorsal vertebra. The thyroid is protected by an opaque covering. Three treatments are given each week. During the first week each treatment lasts five minutes and a dose of 100 R units is given over each field. In each of the three succeeding weeks the duration is increased by five minutes and the dosage by 100 R units at each treatment, the patient thus receiving a total of 2,000 R units in the four weeks. This treatment is contraindicated in debilitated subjects, in cases of marked cardiac insufficiency, and in old persons aged 70 or more.

51. Gastric Examinations.

G. MAINGOT (*Rev. de Méd.*, 1928, No. 5, p. 645) states that in making radiological examinations of the stomach the opaque meals should be stable and homogeneous, denser than and only slightly miscible with water. Preparations which excite gastric secretion, or which are decomposed by it, are useless. Suitable meals are dense, pasty, and made by the incorporation of opaque salts with a farinaceous or mucilaginous fluid. All normal stomachs do not have the same rhythm and time of retention. Short stomachs (*estomacs encorné boeuf*) generally contain only a trace of the meal one and three-quarter hours after its ingestion, while long J-shaped stomachs take a little more than four hours to empty themselves completely. Maingot defines gastric retention or stasis by the pre-ence of the opaque salt in the stomach six hours after the ingestion of 300 c.cm. of a mixture of 100 grams of powdered barium sulphate or 200 grams of gelobarine (a salt preferred by the author) in a neutral excipient. Retention of an opaque meal is not necessarily a sign of pyloric stenosis. Old stenoses are complicated with stasis, but recent ones do not always retard, and sometimes even accelerate, gastric evacuation. Stasis without pyloric stenosis may be intermittent or permanent. Certain extra-gastric conditions of general nervous and psychological origin, such as migraine, also certain emotions and intoxications, influence gastric retention; the same is true of abdominal causes, which may be extraperitoneal, as nephritic colic, or intraperitoneal, as peritonitis. Various conditions affecting gastric retention and secretion, besides those already mentioned, such as appendicitis, cholecystitis, duodenal and gastric ulcers, and neoplasms, are discussed, together with their effects on the radiological picture. From a causal point of view Maingot divides gastric stases into two main groups: the nervous and toxic, associated with a general affection, and those dependent on an abdominal condition. The latter group is divided into extra- and intra-peritoneal, and the last-named is further classified according as the lesion is distant from the stomach, near that organ, is gastric, or is pyloric. A table is given of the various causes of gastric retention.

52. X-Ray Treatment of Prostatic Hypertrophy.

R. OFFENHEIMER (*Urol. and Cut. Rev.*, October, 1928, p. 652), who reports an illustrative case, remarks on the considerable divergence of opinion about the value of *x*-ray treatment in prostatic hypertrophy. The difference in the results is, he says, due partly to the variability of doses. Moreover, there is no agreement as to what forms, and above all in what stages, of prostatic hypertrophy *x*-ray treatment is applicable. As the result of his experience Offenheimer comes to the following conclusions: (1) Moderate *x*-ray doses combined with massage of the prostate improve the irritative symptoms of the first stage, especially the strangury in a great number of cases. (2) On the other hand, this form of treatment does not prevent the further development of the disease, and particularly the occurrence of chronic retention. (3) *X*-ray treatment of the prostate may have a favourable effect in cases of prostatic haemorrhage. (4) Small doses prove ineffective in acute retention, and any form of *x*-ray therapy is useless in chronic retention. (5) The application of large doses aggravates a pre-existing cystitis, makes prostatectomy more difficult, and retards or completely prevents healing of the wound.

Obstetrics and Gynaecology.

53. Vaginal Hysterectomy for Cancer of the Cervix.

T. HEYNEMANN (*Zentralbl. f. Gynäk.*, September 15th, 1928, p. 2330) agrees that the vaginal radical operation in cases of cancer of the cervix is worthy of considerably wider employment than it has had since the introduction of the Wertheim abdominal operation. Heynemann at present performs both operations, preferring the abdominal route when the pubic angle is small and the pelvis narrow, when adnexal tumours are present, when a previous laparotomy has been done, and when involvement of lymphatic glands is expected. Preference is given to the vaginal route in fat patients and those with chronic heart or lung disease, when the growth has extended in the vagina, and when deep-seated infiltration of the parametria is detected. In the vaginal operation great assistance is afforded by a bilateral Schuchardt paravaginal incision; preliminary infiltration of these incisions with adrenaline diminishes as a rule the loss of blood and gives clearer vision. By the vaginal route the paravaginal and paracervical tissues are easily accessible, but infiltrations near the bladder may lead to considerable difficulty. Freeing of the ureters is not always easy, but is not an essential point of the operation, surprisingly large amounts of the connective tissue in this neighbourhood being removable after the bladder and ureters have been displaced upwards. Removal of the ovaries is stated not to be essential for success of the operation. The chief advantage of Wertheim's operation is the greater accessibility of the lymphatic glands; if these are not to play an important part in the operation there is little purpose in subjecting the patient to the more serious risk of the Wertheim procedure. For vaginal hysterectomy anaesthesia by means of nitrous oxide and small amounts of ether is recommended.

54. Inflammation in and around the Pouch of Douglas.

R. CONDAMIN (*Lyon Méd.*, October 21st, 1928, p. 479) believes that there is an etiological as well as a pathological difference between posterior parametritis and inflammation of the pouch of Douglas. Posterior parametritis is secondary to uterine infection, which spreads to one or other utero-sacral ligament through the lymphatics or veins. It causes, at first, contraction of one or both ligaments which produces uterine displacement; this is sometimes followed by stretching of the ligaments, with consequent prolapse. Inflammation of the pouch of Douglas usually follows suppurative generalized parametritis, salpingitis, or oöphoritis; it may cause a series of symptoms involving uterus, bladder, vagina, or rectum, or even in more distant organs. Condamin believes it possible to establish a differential diagnosis. Posterior parametritis is rarely confined to the pouch of Douglas, but almost always extends to the lateral culs-de-sac and the bases of the broad ligaments, the contraction of which is more definite towards the left side, resulting in its resembling hard, rigid cord, often more sensitive than tender. A previous history of puerperal infection, of abortion (particularly when induced), and of other sources of infection may assist in the differential diagnosis. Many pelvic inflammations produce a septic exudation which gravitates towards the pouch of Douglas, where it is absorbed or encysted, causing peritoneal thickening and sclerosis, with contractions leading to chronic inflammation of Douglas's pouch. Condamin believes that occasionally adnexal infections may produce lymphangitis or phlebitis terminating in posterior parametritis, but more frequently a pyosalpinx causes inflammation in Douglas's pouch. Usually it is chronic, with painful retractions and adhesions, which result in the pain characteristic of salpingitis, especially when the Fallopian tubes are small and prolapsed in Douglas's pouch and drag upon the utero-sacral nerves. The weight of a slightly enlarged uterus may produce the same effect. The author believes that the conditions described under the terms "atrophic parametritis" and "periproctitis" are only later developments of inflammation of Douglas's pouch. The former is non-puerperal in origin, and is said to terminate in uterine atrophy. Condamin believes that constipation is due to chronic inflammation of Douglas's pouch, and is not the causative agent.

55. Dangers and Limitations of Support of the Perineum.

ACCORDING to R. T. v. JASCHKE (*Arch. f. Gynäk.*, June 26th, 1928, p. 193) support of the perineum during the passage through it of the foetal head is unnecessary, in normal conditions, with normal pelvis, normal head, normal presentation, and elastic, wide, and distensible soft parts. Where these conditions are not present support is harmful, even in those cases in which it appears most successful. In other words, the perineum, which is easily repaired, is spared at the expense of the deeper parts of the levator ani, which are repaired with difficulty. Even if the levator is not torn, prolonged pressure of the "supported" foetal head injures irretrievably the deep muscle fibres and interstitial tissue of the pelvic floor. Utero-vaginal prolapse, according to this view, is favoured rather than prevented by energetic and prolonged holding back of the foetal head. It has been shown that a spontaneous and even precipitous delivery of a normal foetus through normal bony and soft parts is frequently associated with preservation o. the levator ani, while careful and successful support of the perineum, in spontaneous as well as operative deliveries, is very frequently followed by wide tears of the levator muscle, usually most marked on the side of the foetal occiput. Jaschke concludes that attention should therefore be directed during labour to the deep parts of the muscular pelvic floor, especially the pubo-rectal fibres; perineal tears will become a little (but not a great deal) more frequent, but the levator will be more often spared, and descent and prolapse be rendered less frequent. Where the soft parts are narrow and inelastic, the pubic angle is small, or the head is large, it is advisable either to abandon perineal support or perform a prophylactic deep median episiotomy. Subsequent repair is much easier than that of a torn levator, especially when the lesion is near the anterior end. The author does not go so far as to recommend median episiotomy as a routine in primiparae; it is definitely indicated, he thinks, where infantile characters are well marked in the pelvis or soft parts, in elderly primiparae, and where cephalic flexion is deficient.

56. Ulcus Vulvae Acutum.

S. A. GLAUBERSOHN (*Derm. Woch.*, November 17th, 1928, p. 1766) of Kieff has collected from Russian literature twelve cases of non-venereal ulcer of the vulva described by Lipschütz, including a personal case; nine occurred in virgins and three in married women. In eight cases the characteristic *B. crassus* was found. The disease usually begins with malaise, fever, headache, and shivering; the genital ulcers appear six or ten days later, and are usually mistaken for chancroids. Examination of the blood and internal organs is negative. The ulcers are situated on the labia majora, or more frequently the labia minora. The inguinal glands are not affected. The course is favourable and no complications ensue. As the disease was described by Czapin of St. Petersburg in 1907, at the same time as Lipschütz, Glaubersohn suggests that the disease should be named after both observers.

Pathology.

57. Survival of Leucocytes in Pus.

ACCORDING to S. FRANCESCO (*Il Policlinico*, Sez. Prat., November 26th, 1928, p. 2319) the amoeboid movements of the leucocytes in pus were first described in man by von Recklinghausen in 1863. Achard in 1909 found that the number of leucocytes diminished after incision of the abscess, and also observed that in a case of meningococcus meningitis the number of dead leucocytes increased before death. Francesco has tried to determine whether the leucocytes in all forms of suppuration possessed amoeboid movements; he has also studied the duration of these movements, their relation to intercurrent diseases, and the possibility of there being differences in the behaviour of leucocytes according as the disease ended in recovery or death. His conclusions are as follows. The leucocytes proved capable of movement on the warm stage in all forms of suppuration, with the following exceptions: (1) leucocytes removed by exploratory puncture or during operation from the abscess cavity; (2) in cachectic states which ended fatally. The motility of the leucocytes was most marked on the first day on which the pus was taken, became less on the second day, and had entirely disappeared by the fourth day. If the author's observations are confirmed by others, he is of opinion that the study of the survival of leucocytes in pus, in addition to its scientific interest, will acquire a practical value as an important prognostic guide.

58. The Nature of Anthrax Infection.

G. BOVIDA and E. SCHWARTZ (*Lo Sperimentale*, November 5th, 1928, p. 765) have found that, notwithstanding the vigorous bactericidal action of gastric juice on the vegetative growth of *B. anthracis*, and the anti-germinative action of the intestinal juice on the spores of this bacillus, the failure of the germs to pass out from the gastro-intestinal system into the circulation cannot be ascribed to the action of these juices. After introducing sporulating or non-sporulating *B. anthracis* into the alimentary canal by various experimental methods, it was possible to retrieve from the intestinal contents of the animals both living and virulent spores, and also bacilli derived from them. Since it is demonstrated by the authors' experiments and also by those of other observers that it is not possible for the germs of the organism to pass the digestive mucous membrane and so infect laboratory animals, it is concluded that the failure is due to some impediment more anatomical than functional which is opposed as a barrier to the *B. anthracis* by the intestinal mucous membrane. From the results of their cultural and animal experiments the authors are unable to demonstrate the antagonistic action of *B. coli* on *B. anthracis* described by Sanarelli, and they failed to confirm the views of Carbonieri that *B. anthracis* has a lytic action on *B. coli*.

59. Splenectomy and Experimental Gastric Cancer.

G. C. PERACCHIA (*Rev. Sud-Amer. de endocrinol., immunol. y quimioterapia*, October 15th, 1928, p. 682) reviews the literature, and records experiments on rabbits to determine the effect of splenectomy on the growth of tar tumours of the stomach. Splenectomy was performed, after injection of morphine, on fifteen rabbits, and at the same time drops of tar were injected into the cardiac region of the gastric wall: while a few rabbits also had some drops of tar sprinkled over the peritoneal cavity or injected into the liver or kidneys. Control animals received the same treatment with tar, but did not undergo splenectomy. The results were as follows: Eight animals died from twenty-four hours to five days after the operation without showing anything beyond ulceration of the gastric mucosa. The diminished resistance to cancer resulting from splenectomy, which produced a rapid onset of cachexia, was indicated by the fact that an epithelomatous growth only appeared in two animals which had undergone this operation, while in the others the lesions were merely of an inflammatory type.

Ostelin

the physiologically standardised concentrate of vitamin D

IN FOUR EASILY ASSIMILABLE FORMS

Ostelin in Glycerin
4 minims equivalent in vitamin D value to 1 drachm of cod-liver oil.
DOSE: Children, 1-4 drops t.d s.p.c.; Adults, 2-10 drops t.d.s.p.c.

Ostomalt
(formerly Ostelin with Malt Extract and Orange Juice).
Containing vitamins A, B, C, and D.
DOSE: Children, ½ to 1 teaspoonful; Adults, 1-3 teaspoonfuls t.d.s.p.c.

Ostelin Tablets
Each tablet equivalent to 4 drops of Ostelin with 2 grains of soluble calcium glycerophosphate.
DOSE: 1-4 tablets t.d.s.p.c.

Ostelin Emulsion
Being widely prescribed in place of cod-liver oil emulsions.
DOSE: Infants, ½ teaspoonful, 1-6 times daily; Children, 1 teaspoonfel t.d.s.p.c.; Adults, 1-3 teaspoonfels, t.d.s.p.c.

Also Ostelin Ampoules and Ostelin with Parathyroid Tablets

Glaxo House, 56, Osnaburgh St., London, N.W.1

The
NEW GLAXO
in the White Tin

because it contains added vitamin D is popularly called

SUNSHINE GLAXO

If your patient asks for "Sunshine Glaxo" at the chemist she will be sure of getting *new Glaxo*—

HUMANISED GLAXO

with slightly lowered fat content and added vitamin D

Glaxo House, 56, Osnaburgh St., London, N.W.1

ULTRA-VIOLET IRRADIATION

THE value of irradiated milk for rachitic children and in cases of tuberculosis of the bones has been shown many times. (See *B.M.J.*, March 28th, 1925; *The Lancet*, Jan. 2nd and Dec. 25th, 1926; *The British Journal of Radiology*, Feb., 1926; and the *Journal of Actinotherapy*, June, 1928). But hitherto the process of irradiation has always tainted the final product.

This difficulty has now been overcome by the

"SCHEIDT" PROCESS

in which COLD QUARTZ TUBES

with remarkable U.V. Spectra give an easily controlled and positive activation and leave the products

UNCHANGED in TASTE or ODOUR

Members of the Medical Profession are invited to a demonstration at

THE FOODSTUFFS IRRADIATION CO. LTD.,

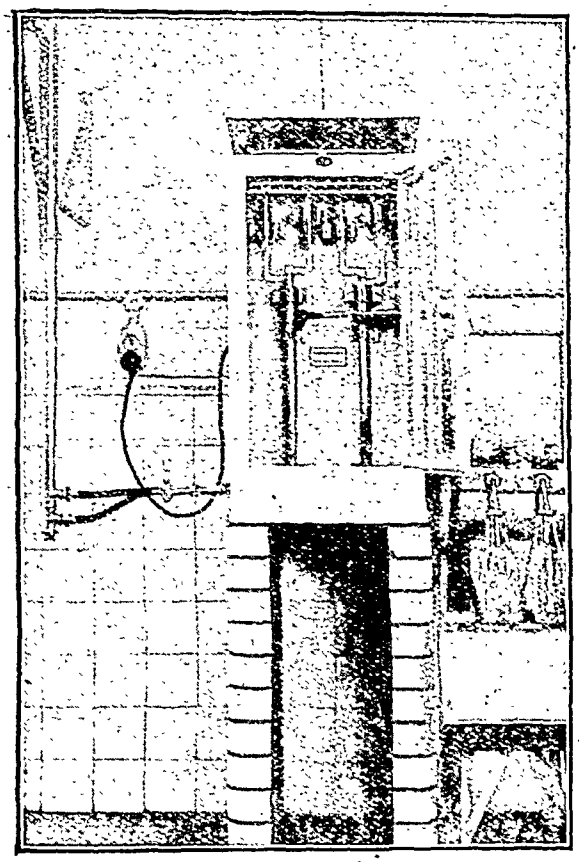
Phone: Museum 0162.



Scheidt Patent 257956

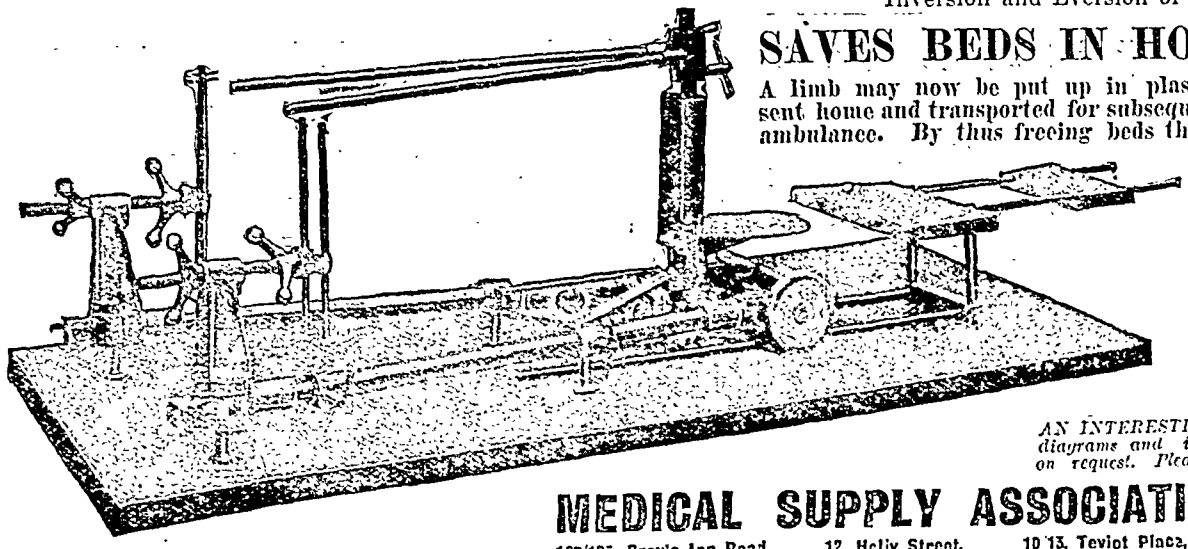
An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopædic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 32 in. × 14 in. × 7 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy

Equipment for Hospitals and Institutions

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope especially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, which delighted Medical Men at the recent B.M.A. Meeting.

MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

The Medical Profession when prescribing "Liquor Carbonis Detergens" SHOULD ADD THE WORD

Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constituents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

NOVOCAIN

The Original Preparation
English Trade Mark No. 276477 (1905).

Local Anæsthesia in Surgical Practice

FRACTURE OF THE RIGHT FEMUR.

Typical Case.

Mrs. S. E. B., aged 71 years.
Diagnosis: Supracondyloid T-fracture of the right femur.
Operation: Incision, reduction, and application of screws.
Anæsthesia: Transverse infiltration block.
Technique of Anæsthesia: Infiltration block, Novocain-Adrenaline 180 c.c. The patient was given no preliminary hypodermic medication. She was placed on the extension apparatus, great care being taken to make her as comfortable as possible. She was held in position by applying the extension screws, and the skin was prepared by painting with iodine. The line of incision—25 cm. in length—was infiltrated, each excursion of the needle bringing its point in contact with the femur. An especially large deposit of solution was made just posterior to the bone in the region of the fracture. The bone was exposed and the fragments gently separated by the use of a scalpel and chisel. In the meantime the traction screws were brought into play, and the lower fragments were gradually brought down to the proper level. One long screw and a stove bolt were introduced, after drilling the bones in order to prevent a recurrence of the displacement after operation, the fractured surface being rather oblique. This patient left the table with a pulse of 80; there was no hæmorrhage, no shock, no pain, and she presented no post-operative complications.

—Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

Full technique of this and one hundred other operations under local anæsthesia will be found in the above work published by Henry Kimpton, 263, High Holborn, London, W.C.1.

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify " Novocain " for your next operation.

WRIGHT'S LYSOL

The quality of WRIGHT'S LYSOL has never been questioned

It is safe to prescribe Wright's Lysol—safe because you know that your patients will then get a pure and highly refined Lysol controlled by the Rideal-Walker test. Wright's contains no free alkali—does not sting or irritate — gives certain results. It is widely used by the profession;

Hospitals and Nursing Homes prefer it.

Tell your patients always to say "Wright's" before "Lysol."

British owned and British made by the makers of the world famed Wright's Coal Tar Soap.

A handy graduated measure is provided with every bottle.

Prescribe HORLICK'S

Even the weakest patients, with virtually no energy to digest food of any kind, can frequently assimilate and retain Horlick's when all other foods are rejected.

THE RESIDENTIAL TREATMENT OF ALCOHOLISM & DRUG ADDICTION

RENDLESHAM HALL

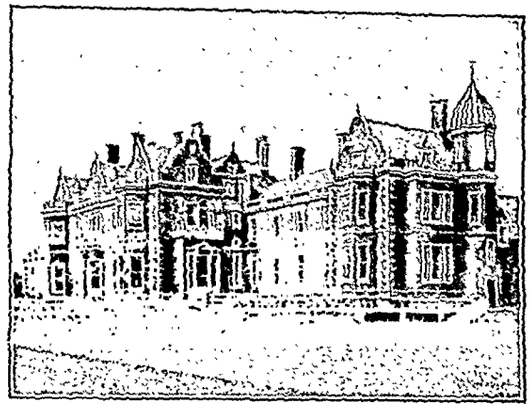
(Postal Address)—WOODBRIDGE, SUFFOLK.

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms, and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated Booklet, giving particulars as to terms, etc., can be had on application to the RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: Wickham Market 16.



RENDLESHAM HALL.

To those desiring to be near London—
The Mansion, Beckenham Park, Beckenham, as carried on for the last twenty years, is available. Booklet and particulars from the Resident Medical Superintendent.

Telephone: RAVENSBOURNE 0648. *Telegrams:* NOROTORIUM, BECKENHAM.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., C.B.E.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard court), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone: No. 56 Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

For terms, etc., apply to the Medical Superintendent

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and out-door recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: *Teignmouth* 289.

NEURASTHENIA.
BELVOIR NURSING HOME, ASTON-ON-TRENT, DERBY.

Private Nursing Home for Neurasthenia and allied Functional Nervous Disorders, for general Convalescent Cases, and those requiring Electrical Treatment.

The Home, a Georgian mansion 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical Treatment, Radiant Heat, X-ray, Ultra-Violet Light, and Massage is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week. For further particulars apply to—
Dr. E. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: *Shardlow* 16.
Dr. Douglas-Morris can be seen by appointment in London.

MAUDSLEY HOSPITAL,
DENMARK HILL, S.E.5.

Telephone: BRIXTON 788.

A CLINIC instituted by the London County Council for Treatment of NERVOUS and CURABLE MENTAL DISORDER. Voluntary patients ONLY RECEIVED.

OUT-PATIENTS—2 p.m.: MEN—Mondays and Thursdays. WOMEN—Tuesdays and Fridays.
IN-PATIENTS: (*a*) 160 beds (both sexes) in wards or separate rooms. (*b*) 13 private rooms (for ladies) with special sitting rooms, garden, and dietary.

Terms:

(*a*) £5 a week, but in case of patients with a legal settlement in the County of London a less sum may be charged according to means.
(*b*) £6 6s. a week.

Terms include (with rare exceptions) all forms of treatment, for which exceptional facilities exist—there being a staff of consultant specialists and the central laboratory of London County Mental Hospitals being attached to the hospital. Inquiries of EDWARD MAPOTHER, M.D., M.R.C.P., F.R.C.S., Medical Superintendent.

EPILEPSY.

Attendance at School is a necessary part of the satisfactory treatment of Epilepsy in Children.

COLTHURST HOUSE SCHOOL

meets all the requirements of children of middle-class parentage. Extensions, made necessary by the success of the school, have created several vacancies. Only bright and intelligent boys and girls are eligible for admission.

Apply to the Medical Superintendent
COLTHURST HOUSE SCHOOL,

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS.

Special Preparations for all Surgical Qualifications.

F.R.C.S.ENGLAND. (Primary & Final.) Ch.M.EDINBURGH M.C.Ch.A.Tab.

F.R.C.S.EDINBURGH. M.S.LONDON.

And all other Surgical Degrees and Diplomas.

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.

¶ Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our courses.

¶ The Surgical Tutors of the College all hold either the M.S.Lond. or F.R.C.S.England, or both, and are highly experienced teachers

¶ The Postal Courses are thoroughly clear, concise, and up to date, and the test questions are carefully selected from those set at previous Examinations, so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time, and much unnecessary reading is saved

LUDFORD (Fouderton Research Student of the Royal Society, and Honorary Lecturer in Cytology, Department of Anatomy and Embryology, University College, London), at UNIVERSITY COLLEGE, LONDON (Gower Street, W.C.1), on THURSDAYS, JANUARY 24th and 31st, FEBRUARY 7th, 14th, 21st, and 28th, at 5 p.m.

Admission free, without ticket.

EDWIN DELLER, Academic Registrar.

ROYAL ARMY MEDICAL CORPS.

TWENTY-FIVE COMMISSIONS in the Royal Army Medical Corps will be offered in January, 1929.

Candidates will be selected for Commissions without competitive examination, and will be required to attend in London towards the end of January for medical examination and interview.

Candidates must be under 28 years of age on February 1st, 1929, and registered under the Medical Acts.

Forms of application and all particulars may be obtained from the Under-Secretary of State, War Office (A.M.D.1), London, S.W.1, and all applications should reach the War Office not later than January 20th, 1929.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian service for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Year of Total Service.
1		3	4	5
		Rs.	Rs.	
Lieut.		500	150	1st
			150	2nd
			150	3rd
			150	4th
Capt.	(i) During first 3 years' service as Captain	650	£15	5th
			£15	6th
			£25	7th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	8th
			£25	9th
			£25	10th
	(iii) With more than 6 years' service as Captain	850	£25	11th
			£30	12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut.-Col.	(i) Until completion of 23 years' total service ...	1500	£30	13th and over
	(ii) During 24th and 25th years' service	1600	-	
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

WAR SERVICE CONCESSIONS.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:

	Per annum.
	£
After 17 years' service for pension	400
„ 18 „ „ „	430
„ 19 „ „ „	460
„ 20 „ „ „	500
„ 21 „ „ „	540
„ 22 „ „ „	580
„ 23 „ „ „	620
„ 24 „ „ „	660
„ 25 „ „ „	700
„ 26 „ „ „	750
„ 27 „ „ „	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. Applications should be submitted as soon as possible. The Selection Committee will meet shortly to make nominations, and the selected candidates will be required to attend a course of instruction commencing on February 4th, 1929.

ROYAL ARMY MEDICAL CORPS.

TWENTY-FIVE COMMISSIONS in the ROYAL ARMY MEDICAL CORPS will be offered in January, 1929. Applications should reach the War Office not later than January 25th.

Candidates will be selected for Commissions without competitive examination, and will be required to present themselves in London for interview and medical examination towards the end of January. They must be under 28 years of age on February 1st, 1929, and registered under the Medical Acts.

Officers of the R.A.M.C. are liable to serve in any part of the world where British Troops are quartered.

Ample opportunities exist in the Army for clinical professional work, both Medical and Surgical, as well as for the study and practice of Hygiene, Pathology, and all the special branches.

The cost of Post-Graduate study, which is compulsory, is met from Army Funds.

Officers serve on an average 3 to 4 years at home to 5 years abroad.

Pay and Allowances.—Pay from £500 to £2,000 a year according to rank and length of service.

Gratuities on retirement.—After 7 years' service £1,000.
„ 15 „ „ £2,800.
„ 18 „ „ £3,500.

Current rates of retired pay range from £372 per annum normally earned by a Major after 20 years' service to £940 per annum, the maximum for which a Major-General is eligible.

The rates of pay and retired pay are subject to periodical variation consequent on fluctuation in the cost of living.

Outfit Allowance.—An officer on joining receives £50 as outfit allowance.

Marriage Allowance.—Officers of 30 years of age and over who are married are entitled to draw special rates of allowances.

A Voluntary Widows' and Orphans' Fund exists for officers of the Corps.

All particulars may be obtained by application, in writing or personally, to The Under Secretary of State, The War Office (A.M.D.1), Whitehall, London, S.W.1.

The Barbados General Hospital.

Wanted, a duly qualified medical practitioner (male) as JUNIOR RESIDENT SURGEON of The Barbados General Hospital (224 beds). A man who has had experience in administering anæsthetics preferred.

Salary £250 per annum, with a temporary addition of 20 per cent., and quarters furnished for a single man, free water, lighting allowance, and no local rates. The appointment is for three years, with three months' notice on either side to terminate the engagement, and first-class passage out (direct from England) will be paid by the Hospital for the full term of service.

Applications, accompanied by a recent medical certificate of physical fitness, and professional and other testimonials, stating age and date of graduation, will be received by Dr. A. A. GIBBONS, at "Balmoral," 34, Prince's Square, Bayswater, London, W.2, and should reach him not later than January 15th, 1929.

Canadian Graduates must be registered in a province, registration in which will entitle them to be registered in the United Kingdom.

Candidates holding a United States degree must be registered in the State of New York.

By Order of the Court of Trustees and Directors,

J. WARD,
Secretary.

General Hospital,
Bridgetown,
Barbados, B.W.I.

County of London.

The London County Council invite applications for appointment as EIGHTH ASSISTANT MEDICAL OFFICER (male) in its MENTAL HOSPITAL SERVICE. Candidates must be under 35 years of age and be registered to practise both in medicine and surgery in England. Further information can be obtained from the Medical Superintendent at the Hospital by letter, or preferably by interview.

Applications, with copy testimonials, should reach the undersigned not later than 10 a.m. on Monday, January 28th.

L. E. FRAQUET,
Clerk to the Guardians.

Board Room,
Union Road,
Leytonstone, E.11.
January 1st, 1929.

The Hospital for Sick Children,

Great Ormond Street, London, W.C.1.

There will be a Meeting of the Joint Committee on Wednesday, January 16th, 1929, to elect an ANÆSTHETIST.

Gentlemen are invited to send in their applications, [illegible] the Secretary, with copies of not [illegible] monials, written specially [illegible] 12 o'clock on Monday, [illegible] medical practitioners and be prepared to take up the duties of the appointment on January 17th, 1929.

The successful candidate will be appointed for a period of one year, and will be eligible for re-election, an honorarium of £15 15s. being voted on the expiration of each year of office, and an allowance of £6 6s. is granted also to provide a substitute during three weeks' annual leave of absence.

All candidates must appear before the Joint Committee at their Meeting on Wednesday, January 16th, 1929, at 4.45 p.m. precisely.

Forms of application and copies of the rules may be obtained from the Secretary.

By Order of the Board of Management,

JAMES McKAY,
Secretary.

December, 1928.

The Hospital for Sick Children,

Great Ormond Street, London, W.C.1.

A RESIDENT MEDICAL SUPERINTENDENT is required on January 17th, 1929.

Gentlemen are invited to send in their application to the Secretary, before 12 o'clock, on Monday, January 14th, 1929, accompanied by copies of not more than three testimonials given specially for the purpose.

The appointment is made for one year, but may be held, subject to re-election, for a period of three years.

Salary £300 per annum, with board-residence in the Hospital, £10 allowance for laundry, and £18 18s. for the purpose of providing a substitute during annual leave.

Candidates must be unmarried and possess a legal qualification to practise, and must have held a responsible Hospital appointment at a General Hospital.

All candidates must be in attendance on Wednesday, January 16th, 1929, at 4.45 p.m. precisely, to appear before the Joint Committee, if required.

Forms of application and copies of the rules may be obtained from the Secretary, at the Hospital.

By Order of the Board of Management,

JAMES McKAY,
Secretary.

December, 1928.

London Hospital, E.1.

There is a vacancy for a DENTAL ANÆSTHETIST in the London Hospital and Dental School, to attend one morning a week. A small honorarium is attached to the appointment. Further particulars may be obtained from the House Governor, London Hospital, E.1.

E. W. MORRIS, House Governor.

Borough of Hartlepool.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH, SCHOOL MEDICAL OFFICER, AND TUBERCULOSIS OFFICER.

The Council invite applications for the above appointments.

In addition to the qualifications prescribed by any statute, candidates must be experienced in the treatment of Tuberculosis and also be either registered in the *Medical Register* as the holder of a Diploma in Sanitary Science, Public Health, or State Medicine, or must have had not less than three years' experience in the duties of a Medical Officer of Health.

The offic[illegible] will be required to undertake the [illegible] Medical Officer under th[illegible] Council for the Hartlepool Dispensary, and for the area covered by the Dispensary area.

The appointment will be subject to the provisions of the Sanitary Officers Order, 1926, and to the approval of the Government Departments concerned. It will be a whole-time appointment (the person appointed will not be permitted to engage in private practice), and will be determined by three calendar months' notice on either side.

Inclusive salary £800 per annum, to be apportioned in respect of the offices held, and subject to deduction under the Local Government and Other Officers Superannuation Act, 1922.

Applications, accompanied by copies of not more than two recent testimonials, must reach the undersigned not later than the 23rd inst.

J. W. PORTER,
Town Clerk.

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. PARTNERSHIP.—The third share of a very old-established mixed-class Practice, in a pleasant London suburb, is for disposal owing to the retirement (through ill health) of the Junior partner. Held 24 years by remaining. Cash receipts average about £2,700 p.a., including appts. producing £340 and panel of 1,000. Visits 3/6 to 21/-. Good house available, with ample accommodation. Rent £85 on lease. Premium 2 years' purchase. Excellent scope.
2. LONDON, SOUTH-WEST. — RESIDENTIAL DISTRICT. — PARTNERSHIP.—A three-tenths share, to commence with, is offered in a rapidly increasing good mixed-class Practice, producing about £2,500 p.a., including panel of over 2,000. Surgery fees 2/- to 5/6, visits 3/6 to 5/-. Suitable corner house, with 2 reception, 6 bedrooms, etc., consulting room, and dispensary. Small garden. Rent on lease £100 p.a. Six months' preliminary assistantship. Scotch Graduate, having Hospital experience, essential.
3. LONDON, NORTH-WEST. — GOOD RESIDENTIAL SUBURB. — Very sound well-established non-dispensing, non-panel PRACTICE, held many years by present incumbent, who is retiring owing to advancing age. Average cash receipts for the past three years £2,222. *Exceptionally good residence, with ample accommodation.* Price for freehold £3,750. Premium 1½ years' purchase.
4. KENT.—GROWING DISTRICT, within 15 miles of London.—PARTNERSHIP.—A one-half share is for disposal in a very sound chiefly better and middle-class Practice, established many years, and held by the remaining partner over 4 years. Gross cash receipts for the past three years £2,528, including panel of 900. No appointments. Fees from 3/- to 21/-. Midwifery 3 to 30 guineas (about 25 cases yearly). Very suitable modern house, with 2 reception, 4 bedrooms, good bathroom, etc. Consulting room. Electric light. Small garden. Garage. Price for freehold about £2,100, nearly all of which could remain on mortgage. *Good sport and schools, and excellent social facilities.* Premium 2 years' purchase.
5. NOTTINGHAM.—Good middle-class PRACTICE offering good scope and having small panel which could be largely increased. Gross cash receipts about £400 per annum. Fees 3/6 to 21/-, medicine extra. Very good modern corner house in pleasant residential district. Rent on lease £80 p.a. Premium 1½ years' purchase.
6. ESSEX.—SMALL COUNTRY TOWN.—Well-established and increasing PRACTICE, producing for the past twelve months £768, including panel of 525, and appointments worth over £60 p.a. Advice and medicine chiefly 3/6 to 7/6, visits 3/6 to 21/-, medicine extra. Mids. (discouraged) 2 to 5 guineas. Exceptionally nice house, with lounge hall, 3 reception, 5 bedrooms, and good professional rooms and usual offices. Hot water supply, electric light. Large garden, with tennis court. Garage for two cars. All in perfect order. Price for freehold £3,100. Premium 1½ years' purchase.
7. LANCASHIRE.—SUBURB OF LARGE TOWN.—Old-established PRACTICE, held by Vendor 30 years. Average income for the past twelve months £1,500, including panel of nearly 1,500. Fees 2/6 to 10/-. Very good house, standing in its own grounds, and containing 3 reception, 4 bedrooms, dressing room, 3 professional rooms. Central heating. Electric light. Garden, with greenhouse. Garage for 3 cars. Price for leasehold £2,100, of which about £1,500 could remain on mortgage. Premium 1½ years' purchase, part by instalments.
8. LONDON, NORTH.—OUTLYING RESIDENTIAL SUBURB.—PARTNERSHIP.—*A one-third share* (to commence with) is for disposal, owing to the retirement of the senior partner, in sound middle-class Practice, situated in rapidly developing district. Income for the immediate past year £2,124. Consultations 3/6 to 10/6, visits 4/6 to 21/-. Good freehold house, price £1,500; or would be rented on lease at £90 p.a. Low expenses. Premium 2 years' purchase.
9. OUTLYING WESTERN SUBURB.—Old-established mixed general PRACTICE. Income for the immediate past year about £2,300, including panel of between 1,400 and 1,500. Fees 3/6 to 10/6. Midwifery from 3 gns. The district is rapidly developing and there is *great scope. Good house*, with garden and garage. Price £2,000. Premium £3,500.
10. LONDON, S.E.—Outlying Suburb.—Very well-estab. growing mixed general PRACTICE, situated in pleasant district within easy reach of town. Gross cash receipts for immediate past twelve months nearly £2,650. Panel of 2,120. Appts. worth about £60 and stated to be transferable. Fees 2/6 to 7/6. Midwifery from 3 gns. (about 40 cases yearly. *Moderate expenses. Seven-roomed house, with kitchen*, 2 waiting rooms, dispensary, and consulting room. Garden. Brick-built garage. Price for freehold £1,500. Premium £4,500.
11. SOUTH OF ENGLAND.—FAVOURITE SEASIDE RESORT.—Mainly better-class PRACTICE, *producing for the last twelve months about* £700, and rapidly increasing. Panel of 150. One appt. worth about £40 p.a. Fees 3/6 to 7/6. Only a few cases of midwifery, 2 gns. upwards. Good house in excellent repair, with 2 reception, 5 bedrooms, etc. Electric light. Garden. Garage. Price for freehold £2,300. Premium £1,400.
12. MIDLANDS.—UNOPPOSED COUNTRY PRACTICE, situated in good hunting centre. Gross cash receipts for past 12 months about £1,000 p.a., including panel of 600. Advice and medicine from 3/6, visits 3/6 upwards, with medicine extra. Lowest midwifery 2½ gns. Exceptionally attractive house, with oak panelling, etc., 2 reception, 10 bedrooms, and professional rooms. Well-stocked garden of 1½ acres, and 12 acres of grassland. Recently re-decorated throughout. Electric light. Price for freehold £4,500, of which £2,200 could remain on mortgage. Premium 1½ years' purchase.
13. CHANNEL ISLANDS.—Old-established general PRACTICE. Present income approximately £700, but large scope. Advice and medicine 3/6 to 10/6, visits and medicine 5/- to 15/-. Midwifery refused. Commodious house, with 2 reception, 6 bedrooms, etc. Vendor's freehold. Good schools. Price for practice and house £3,000.
14. WEST OF ENGLAND.—Very easily worked unopposed Country PRACTICE. Gross cash receipts for immediate past 12 months £657, including panel of 500. Fees from 2/6 to 12/6. Midwifery 3 to 5 gns. *Nice house*, with 2 reception, 6 bedrooms, etc., professional rooms. Large garden and paddock. *Price for freehold* £1,200. Premium 1½ years' purchase.
15. BORDERS OF NORFOLK AND SUFFOLK.—Old-established middle-class PRACTICE, *producing about* £1,100 p.a., including panel of over 500. Visits 3/6 upwards. Midwifery from 2 gns., about 30 cases. Modernized old country house, with ample accom. and large garden; e.l.; all in good order. Price for f'hld. £2,500. Prem. £1,500.
16. DERBYSHIRE.—PARTNERSHIP.—A half share in a very sound panel and club practice, producing £3,200 p.a. Panel of over 3,000. Fees 3/6 to 5/-, medicine extra. Expenses small. Modern house, in good order, with pleasant garden. Garage. *Price for freehold* £1,500, part on mortgage. Premium £3,200, half down and balance by instalments over 4 years.
17. LANCS.—In a rapidly growing good-class suburb of large town (pop. nearly 200,000), a very old-estab. PRACTICE, held by Vendor over 30 years, and averaging about £900 p.a., including Union (£80, *with prospect of increase shortly*) and panel of nearly 1,000. There is a surgery in centre of town to which bulk of practice and panel work is attached. Private residence contains 2 reception, 3 bedrooms, bathroom, etc., and small garden. Both Vendor's properties. Price £1,750, £900 on mortgage, or would be rented. Prem. 1½ yrs.' pur.
18. WILTSHIRE.—Unopposed old-estab. Country PRACTICE, situated in very pretty district and averaging £700 p.a., including Union appt. £70, and panel producing £450. *Nearest opposition 3½ miles.* Railway station 1 mile. House stands in own grounds of 1½ acres, with tennis court, garage, etc., and contains surgery, 3 reception, 5 or 6 bedrooms, bathroom (h. & c.). Electric light plant installed. Vendor's freehold, price £2,500, all of which could remain on mortgage if wished. Premium £1,050.
19. MANCHESTER.—Rapidly developing outlying suburb. Good middle- and working-class PRACTICE, increasing and producing for the last 12 months over £1,500. Panel of 700. Fees from 3/6. Particularly good house, specially built, and containing 3 reception, 5 bedrooms, etc. Electric light. Garden. Garage. Price £3,550, *part on mortgage.* Premium £2,250.
20. ESSEX COAST.—FAVOURITE RESORT.—PARTNERSHIP.—A one-third share to commence with in an *old-established middle-class* Practice. Average income of about £2,800. Panel of 600. Visits 4/6 to 21/-. Little midwifery. Suitable accommodation can be obtained. Premium 2 years' purchase.
21. BEDFORDSHIRE.—Small Country PRACTICE, at present producing at the rate of £400 p.a., but offering good scope. Fees 3/6 to 10/6, medicine extra. Good house, with 2 reception, 6 bedrooms, etc. Separate entrance to professional rooms. Can be rented on lease. Premium £250, or practice and house will be sold for £1,050.
22. SOUTH COAST.—FAVOURITE HOLIDAY RESORT.—Well-established non-dispensing PRACTICE. Average income about £1,100, including panel of 1,200. Consultations 2/6 to 10/6, visits 3/6 to 21/-. Practically no midwifery. Very good house, in best position on sea-front. Price for leasehold (*with 20 years to run at a ground rent* of £4 p.a., and renewable) £2,250. Premium £1,800.
23. KENT.—COAST TOWN.—Well-established mainly industrial PRACTICE. Steady average income of over £1,600. Panel of 1,350. Advice and medicine mainly 3/- and 5/-, and a few at 7/6; visits and medicine from 3/6 to 21/-. Convenient house, with 5 bedrooms. Rent on lease £100 p.a. Premium 1½ years' purchase.
24. RIVERSIDE TOWN, within 60 miles of London.—Well-established upper and middle-class PRACTICE, producing about £1,600 p.a., including panel of 200. Surgery fees from 2/6, visits 3/6 to 21/-. Little midwifery. Good house, with large garden. Garage. Rent on lease £100 p.a. Premium £2,200.

[illegible]nced ASSISTANT, with London qualifications, for Suffolk. Unmarried, aged 25 to 30. Must have ts. Good salary, and prospect of partnership later.

REQUIRED.—Indoor ASSISTANT (or outdoor by arrangement) for Country Practice in Suffolk. Must be English, and pref. Bart's man. Salary £300 p.a. indoor, and equivalent outdoor.

REQUIRED.—Outdoor ASSISTANT, married, for Country Practice in Lincolnshire. Salary £400 p.a., with unfurnished house.

Full Schedule of Terms and Conditions will be forwarded on application.

Prescribe this Coffee in Diuresis

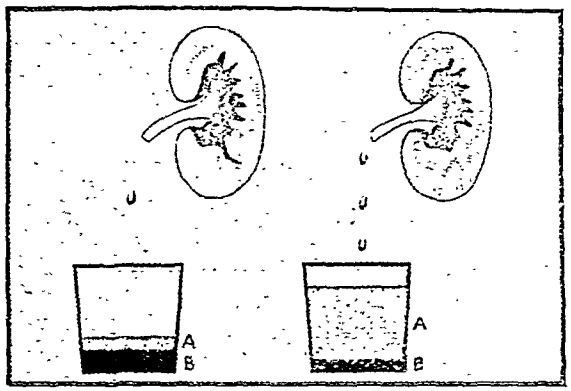
H.A.G. COFFEE

GUARANTEED

97%

DECAFFEINIZED

WILL NOT AFFECT THE KIDNEY



The kidney on the right is influenced by caffein. It is compelled to work harder than normal, and excretes a larger amount of Urine (A). Yet the ual, while the amount of compact substances of Dr. K. B. Lehmann, of the University of ". Tiffenau and H. Busquet, of the Academy of Science, Paris).

PHYSIOLOCICAL research has definitely determined that the caffein in coffee causes diuresis by stimulating the kidney parenchyma and increasing blood pressure.

You know how hard it is to make your patients abstain from drinking coffee or tea—even when they know that it is bad for them.

In such cases H.A.G. Coffee can be confidently recommended. Being 97% decaffeinized, H.A.G. Coffee does not contain enough of the drug to be harmful in even the most acute kidney conditions.

Price per large "Household Size" tin. Bean or Ground, - 3/2.

A DELICIOUS BLEND

Harmless though it is, H.A.G. Coffee is by no means a substitute. It is REAL coffee blended from the finest varieties. But all the original deliciousness is retained—because the caffein is extracted from the raw beans BEFORE ROASTING.

Thousands of physicians abroad have found H.A.G Coffee a safe and effective prescription for every condition where caffein would be harmful. They have found also that their patients usually prefer H.A.G. Coffee to their customary coffee. Your patients will enjoy it too.

Sample tin supplied free to the Medical Profession, also an interesting and valuable booklet entitled "Contra Indications of Caffein."

H.A.G. COFFEE CO., LTD.,

40 Theobalds Road, London, W.C.1

'Phone: MUSEUM 0304

Mendel and Wardell determined that "the addition of strong coffee to a purin-free diet caused a marked increase in the excretion of uric acid." They were further able to prove, by using decaffeinized coffee, that caffein alone causes this increase. (*Journal of the American Medical Association*, Vol. LXVIII, pp. 1805-1807)

Superiority of

Pure, Natural Lævo-Ephedrine

Physiological experiments (*Lancet*, Aug. 4th, 1928, *page* 226, *and Archiv für Experimentelle Pathologie und Pharmakologie*, 1928, *138*, 209) indicate that

(1) Pure, natural lævo-ephedrine is at least four to five times as active, physiologically, as dextro-ephedrine.

(2) Pure, natural, lævo-ephedrine is about twice as active, therapeutically, as synthetic ephedrine.

BURROUGHS WELLCOME & Co.

Ephedrine Preparations

(a) Present pure, natural lævo-ephedrine made from the genuine drug—Ephedra ;

(b) Are free from pseudo-ephedrine and other subsidiary alkaloids ;

They therefore possess greater physiological activity than synthetic ephedrine.

Their activity is constant and uniform.

'Pitocin' AND 'Pitressin'

AS a result of many years' research work, Parke, Davis & Co. have isolated the oxytocic and the pressor principles of the pituitary (posterior lobe) gland. The oxytocic principle (originally known as Oxytocin) is now available for medical use under the name 'PITOCIN,' and the pressor principle (originally known as Vasopressin) is also available under the name 'PITRESSIN.'

'Pitocin,' being almost entirely free from the pressor principle of the pituitary gland, is indicated in those obstetrical cases in which it is desired to avoid raising the blood-pressure, and particularly where there is reason to fear so-called "pituitary shock." (*Vide "The Lancet,"* October 6, 1928, p. 694.)

Each c.c. of 'Pitocin' contains 10 oxytocic units, and it is thus identical in activity with 'Pituitrin.'

'Pitressin' is indicated for the treatment and prevention of surgical shock, for the control of diabetes insipidus, and in cases of post-operative intestinal distension. Each c.c. contains 20 pressor units (one pressor unit being the pressor activity exhibited by 0·5 mgm. Standard Powdered Pituitary, U.S.P.). 'Pitressin' has thus double the pressor activity of 'Pituitrin.'

'Pitocin' and 'Pitressin' are available in boxes containing 6 or 12 ampoules of ½ c.c. or 1 c.c.

PARKE, DAVIS & CO. 50 BEAK ST., LONDON, W.1.

RELIEF!

....from the moment it is applied!

Relief, too, for the busy nurse, who knows from experience that ANTIPHLOGISTINE applied warm and thick can be depended upon to supply and maintain a uniform degree of moist heat during her entire off-duty period.

By virtue of the synergistic combination of its ingredients the osmotic action of Antiphlogistine begins promptly, activating the superficial circulation, decongesting and allaying the painful processes without irritation, and inducing natural and restful sleep.

Prescribed by the Medical Profession the world over for more than a quarter of a century in preference to fomentations and messy flaxseed poultices because its efficacy in the treatment of inflammations of both superficial and deep-seated structures has never been questioned.

Antiphlogistine

A proven adjuvant in the treatment of Pneumonia.

THE INDIAN JOURNAL of MEDICAL RESEARCH

EDITED BY

THE DIRECTOR-GENERAL, INDIAN MEDICAL SERVICE, THE PUBLIC HEALTH COMMISSIONER WITH THE GOVERNMENT OF INDIA, AND THE DIRECTOR, CENTRAL RESEARCH INSTITUTE, IN COLLABORATION WITH

leading authorities on Tropical Medicine.

The Indian Journal of Medical Research is published quarterly. Each number contains about 200 pages, and is illustrated with Plates in Colour and Half-tone, and with Diagrams and Charts, and it is the only medium publishing the results of the best medical research work being carried on by leading scientific medical men in India and the East.

THACKER, SPINK & CO., P.O. Box 54, CALCUTTA.

W. THACKER & Co. 2, Creed Lane, E.C.4, London Agents.

SECOND IMPRESSION. Cr. 8vo. 168 pp. 4s. 6d. net; postage 4d.

THE ELEMENTS OF MEDICAL TREATMENT

By ROBERT HUTCHISON, M.D., F.R.C.P.,
Physician to the London Hospital.

"A model of brevity, clearness, and sound judgement."
—*British Medical Journal.*

ALSO BY THE SAME AUTHOR.
Crown 8vo. 2s. 6d. net; postage 2d.

SOME PRINCIPLES OF DIAGNOSIS. PROGNOSIS AND TREATMENT

"There can seldom have been more interesting and shrewdly worded advice than that closely packed in these pages."
—*British Medical Journal.*

Large 8vo. 223 pages, with 261 Illustrations, some of which are in Colour. 21s. net; postage 6d.

DEMONSTRATIONS OF

PHYSICAL SIGNS IN CLINICAL SURGERY

By HAMILTON BAILEY, F.R.C.S.Eng.,
Surgeon, Dudley Road Hospital, Birmingham.

The Illustrations form a prominent feature of the volume, and much care has been taken to render them as accurately as possible.

"It was time a book of this nature was available in English, and the author is to be congratulated upon the success with which he has carried out his task. A feature of the book is the abundance of illustrations, all of which are informative."—*Lancet.*

"We have nothing but praise for this book."—*Edin. Med. Journ.*

Bristol: JOHN WRIGHT & SONS Ltd. [Catalogue free.] London: SIMPKIN MARSHALL Ltd.

JOHN BALE, SONS & DANIELSSON, Ltd.

THE CHILD OF CIRCUMSTANCE—THE MYSTERY OF THE UNBORN. By ALBERT WILSON, M.D.Edin., Fellow late President of the Royal Medical Society, Fellow of the Royal Society of Medicine, etc. With Forewords by The Rev. R. J. CAMPBELL, D.D., and JOSEPH SHAW BOLTON, M.D. F.R.C.P., D.Sc. 6. Illustrations. 15s. net; post free, inland 15s 9d.

This work refers to the last hundred years and the changes which have occurred since then. The author is interested in criminals and has made a study as to their cause, their behaviour, and their cure.

The aim of this book is to deal with the criminal from a scientific point of view, to ask what he is and why he is.

THE PRINCIPLES OF ANTE-NATAL AND POST-NATAL CHILD HYGIENE. By W. M. FELDMAN, M.D., B.S., M.R.C.P.Lond., F.R.S.Edin. With 161 Illustrations and 14 Plates, including over 10 Portraits 25s. net; post free 25s. 9d.

"The author has attempted, and has succeeded in, the difficult task of producing a book which will interest alike paediatric physicians, lay workers at infant welfare centres, students of ante-natal care and welfare, and all concerned with the well-being of children. The general practitioner will find in it answers to the innumerable questions of young parents. . . These and other subjects are dealt with concisely but in detail, the attractive style of the writing preventing the weariness in reading that would otherwise be inevitable."—BRITISH MEDICAL JOURNAL.

SHORT ESSAYS ON MEDICAL TOPICS.

By C. O. HAWTHORNE, M.D. 4s. 6d. net; post free 5s.

"This is, in brief a collection of well-written and thoughtful papers on medical matters and the medical life—not to be looked through once and put aside, but kept in a handy place for occasional reading, with other books which are opened with expectation and studied with profit."—BRITISH MEDICAL JOURNAL.

CÆSAREAN SECTION. With a Table of 120 Cases.

By HERBERT R. SPENCER, M.D., B.S., F.R.C.P. 6s. net; post free 6s. 6d.

"A valuable addition to obstetric literature from one who is both an expert obstetrician and a careful and most successful surgeon."—JOURNAL OF OBSTETRICS AND GYNÆCOLOGY.

OUTLINES OF SCIENTIFIC ANATOMY.

By Dr. WILHELM LUBOSCH, Prof. of Anatomy in Würzburg. **For Students of Biology and Medicine. Designed to supplement the usual Textbook Teaching.**

Trans. by Dr. H. H. WOOLLARD M.D., Prof. of Anatomy, University of Adelaide, formerly Assistant Professor of Anatomy, University College, London. 66 Illustrations. 21s. net; post free 21s. 9d.

"An excellent translation of an extremely valuable book, in which Professor Lubosch discusses, in a most illuminating manner, the outlines of the science of anatomy."—EDINBURGH MEDICAL JOURNAL.

HOSPITALS AND THE STATE. A Popular Study of the Principles and Practice of Charity. By R. WESTLAND CHALMERS, M.B. Ch.B., D.P.H. 6s. net; post free 6s. 6d.

This treatise purports to describe the beginnings and growth of the modern hospital from a domiciliary origin in the ancient custom or convention of hospitality. It is presented as a short history from Anglo-Saxon and Norman times down to the system of co-ordinated hospitals suggested by the Report of the Medical Consultative Council of the Ministry of Public Health 1920 and the present-day machinery of State medical services. The principal object is to depict, in this institutional growth, the corresponding advance of the spirit of charity towards its public and social equivalent in the State as the organ of humanity.

MANUAL OF EMERGENCIES. Medical, Surgical, and Obstetric. Their Pathology, Diagnosis, and Treatment

By J. SNOWMAN, M.D., M.R.C.P. 10s. net; post free 10s 6d. 2nd. Ed.

"We are convinced that no general practitioner who has seen this work would willingly be without it."—POST-GRADUATE MEDICAL JOURNAL.

SURGICAL TREATMENT OF PULMONARY AND PLEURAL TUBERCULOSIS. By J. GRAVESEN, M.D. (Copenhagen), Med. Superint., Vejlefjord Sanatorium, Denmark. With a Foreword by S. VERE PEARSON, M.D., M.R.C.P., Res. Physician, Mundesley San. 87 Illus. (3 in col.). 10s. 6d. net; post free 11s. 3d.

"Dr. Gravesen's book fills a gap . . . will remain a standard work on this subject for years to come."—LANCET.

THE HISTORY OF BRITISH MIDWIFERY. 1650-1800.

By HERBERT R. SPENCER, M.D., B.S.Lond. 15s. net post free 15s. 9d.

"It contains information which is not to be found elsewhere, and which would alone entitle it to be regarded as a standard work on the subject. . . An important and attractive volume."

—BRITISH MEDICAL JOURNAL.

MEDICAL AND ALLIED TOPICS IN LATIN POETRY.

By H. OPPENHEIMER, D.Lit., LL.D., Ph.D., M.D. 30s. net; post free 30s. 6d.

"A really interesting book, which, although in no sense a medical history, none the less throws a remarkable light upon the medical practice and medical superstitions of the past, especially upon those of Imperial Rome."—LANCET

A TREATISE ON KALA-AZAR. By UPENDRANATH BRAHMACHARI, K.-i.-H. (Gold), Rai Sahib, M.A., M.D., Ph.D. 13 Plates (7 coloured). 21s. net; post free, inland 21s. 9d., abroad 22s. 10d.

A new book embodying all the latest facts known about the probable transmission of the disease and the latest advances in its treatment.

"The first impression which one obtains on glancing through this sumptuous book is the extremely high standard of publication reached . . . We must warmly congratulate Dr. Brahmachari on the publication of this volume."—INDIAN MEDICAL GAZETTE.

83–91, GREAT TITCHFIELD STREET, LONDON, W.1.

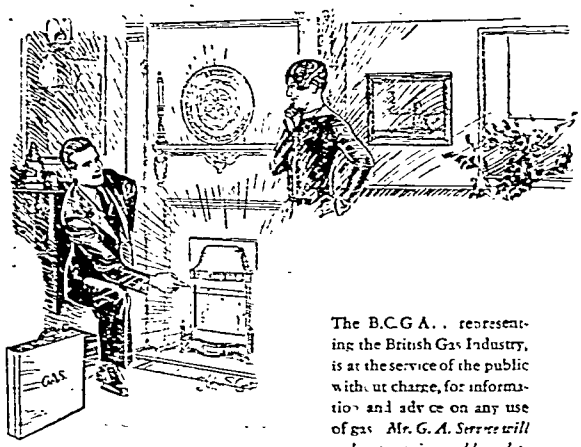
"Gas fires ventilate rooms . . .



Mr. G. A. SERVICE on "Warmth and Ventilation."

The B.C.G.A. . . representing the British Gas Industry, is at the service of the public without charge, for information and advice on any use of gas. *Mr. G. A. Service will welcome enquiries addressed to him at* The British Commercial Gas Association, 28, Grosvenor Gardens, London, S.W.1

". . . . There are no fumes from the gas fire . . . . There are products of combustion, of course, as there are from *any living flame* . . .

But they immediately pass up the chimney or flue. And as they rise they cause a gentle upward flow of used air from the room—a system of ventilation more perfect even than that of the open window. That's why—as our scientists have proved—every room should have a chimney or flue reaching up to the roof . . . . every room an open fire : . . . . . Yes, *a gas fire*, which has living flames, gives radiant heat, ceaseless ventilation, and makes no smoke or dirt."

GAS

OUR ANALYSIS
of
BAD PAYERS

For 40 years we have been specializing in the collection of unpaid fees for the Medical and Dental Professions *only*, and we analyse the non-payers as follows:—

35% are not intentionally dishonest.

10% deliberately trade on the good nature of Doctors and Dentists.

10% have imaginary grievances.

5% have genuine grievances.

5% do not pay because bills are sent to the wrong person.

10% think a practitioner cannot sue for fees and delay until forced to pay.

25% are dishonest in various ways—bulk can be best described as "Bilkers."

As we collect debts "WITHOUT OFFENCE," we invariably change all bad payers into good payers. Let us help you with your unprofitable clients—don't bother to write, just send your card —we will send full particulars.

Intestinal Disinfection

ALIMENTARY TOXÆMIA AND NEURASTHENIA

NEURASTHENIA is no doubt a comprehensive term which includes several affections of different ætiology.

In many of the cases alimentary toxæmia plays a considerable part; the digestion is upset and flatulence is frequent, the bowels are fickle in their action, and the indican and ethereal sulphates in the urine are markedly increased—sure signs of putrefactive changes in the bowel.

In this class of cases intestinal disinfection is one of the principal lines of treatment to be adopted, and for this purpose nothing surpasses the use of Kerol Capsules.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

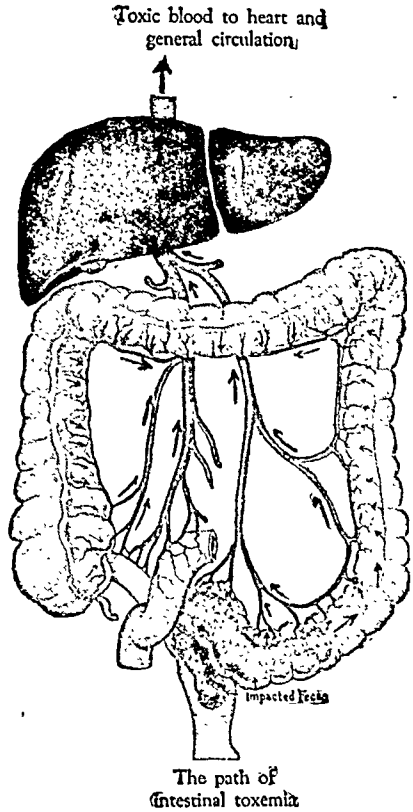
Dissolves Intestinal Toxins



The path of intestinal toxemia

Not the least valuable of its properties is the behaviour of Nujol toward intestinal toxins.

If a watery solution of indol be shaken up with Nujol, more than half the indol is quickly taken up. Nujol readily dissolves this and other waste and poisonous substances, many of which are more soluble in Nujol than in water. Once absorbed in Nujol they cannot be absorbed by the system, as Nujol itself is non-absorbable.

The brownish colour of Nujol as seen in the stool is partly due to toxins which it holds in solution.

Nujol is a safe and effective treatment in all types of constipation and intestinal toxemia.

THE FRENCH NATURAL MINERAL WATER

VICHY-CELESTINS

And the other State Springs of Vichy
(Property of the FRENCH STATE)

FERMENTATIVE DYSPEPSIA.

When the secretion is vitiated in quality, and the motricity of the stomach weakens, that organ dilates, and the gastric stagnation allows the micro-organisms of many ferments to develop. Quite a series of acids are then to be met with (butyric, lactic, acetic, etc.), which not only irritate the mucosa, but further, after their passage into the intestine, become absorbed by the lymphatics and swept into the circulation. **Vichy-Celestins**, by its slightly stimulating action, clears out the stomach, and this avoids stagnation and consequent fermentation. As, in addition to doing this, it modifies stomachal metabolism, the secretions return little by little to their normal physiological condition.

CAUTION.—Each bottle from the STATE SPRINGS bears a neck label with the word "VICHY-ETAT" and the name of the SOLE AGENTS:

INGRAM & ROYLE, LIMITED,
Bangor Wharf, 45, Belvedere Road - - - - - - - London, S.E.1

INSULIN "A.B."

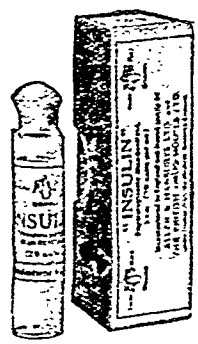
TRADE A B MARK **Brand**

"A.B." Insulin was the first British Insulin available for use by the Medical Profession and after almost five years retains its reputation as the Insulin which can be relied on to give consistently satisfactory results. The supremacy of "A.B" Insulin is due entirely to the stringently high standards of purity, therapeutic efficiency and stability self-imposed by its manufacturers.

"A.B." Insulin connotes:

Uniformity of unitage.
Full potency and stability in all climates.
Purity and complete sterility.
Absence of reaction-producing proteins with consequent noteworthy freedom from unpleasant by-effects.

The activity of "A.B." Insulin is guaranteed by the most complete physiological tests and standardisation on the basis of the accepted unit. Before issue, each batch is passed under the authority of the Medical Research Council.



Supplied in two strengths:

20 units per c.c.
Packed in bottles containing:
5 c.c. (100 units or 10 doses) 2/8 each
10 c.c. (200 „ 20 „) 5/4 „
25 c.c. (500 „ 50 „) 13/4 „

40 units per c.c.
Packed in bottles containing:
5 c.c. (200 units or 20 doses) 5/4 each

Full particulars and the latest literature will be sent free to members of the Medical Profession.

NATURAL

CARLSBAD SPRUDEL-SALT

Prepared only by the Municipality of Carlsbad from the World-famous Sprudel "Spring" at Carlsbad

(IN CRYSTALS OR POWDER)

Is the Only Genuine CARLSBAD SALT.

Largely prescribed in cases of Chronic Gastric Catarrh, Hyperaemia of the Liver, Gall-stones, Chronic Constipation, Diabetes, Renal Calculi, Gout, and Diseases of the Spleen, arising from residence in the Tropics or Malarious Districts.

Medical Practitioners should kindly note, when prescribing, to specify "Carlsbad SPRUDEL-Salt" on account of the many artificial preparations upon the market.

The wrapper round each bottle of genuine Salt bears the Signature of the Sole Agents:

INGRAM & ROYLE, LTD.,

BANGOR WHARF, 45, BELVEDERE ROAD, LONDON, S.E.1.

And at LIVERPOOL and BRISTOL.

Samples and Descriptive Pamphlet forwarded on application.

UNG. SEDRESOL (Ferris).

A Valuable Sedative Antiseptic and Healing Ointment.

UNG. SEDRESOL is a combination of the products obtained by the destructive distillation of the wood and bark of the *Betula alba* in combination with Oxide of Zinc and Antiseptics.

It is specially indicated in Eczema, Psoriasis, Erysipelas, Shingles, Erythema, Seborrhœa, Dermatitis, Pruritus Ani and Vulvæ, and in Inflammations and Eruptions of the Skin and in Burns and Scalds.

UNG. SEDRESOL is supplied to the Medical Profession at the following prices:—

¼-lb. Jars, 1/8 each; ½-lb. Jars 3/- each; 1-lb. Jars, 5/9 each; 2-lb. Jars, 11/- each; 4-lb. Jars, 21/- each. (*Empty Jars allowed for on return.*)

SEDRESOL SOAP (Ferris).

A pure superfatted soap for the skin containing the same medication as Ung. Sedresol.

Price: 10d. per tablet, 9/6 per dozen. 30/- per dozen boxes of 3 tablets.

(The word "Sedresol" is registered under the Trade Marks Act and is the sole property of Ferris & Co., Ltd.)

FERRIS & COMPANY, Ltd.

BRISTOL

Wholesale and Export Druggists and Manufacturing Chemists.

Composition

The discovery of a solid emulsifying agent as carrier for cresylic acid made possible a solid form of Lysol, known as Lysolats.

The pH (Hydrogen Ion Concentration) Test for Lysolats gives a neutral reaction, not acid as in the case of liquid lysols.

The Rideal-Walker Index shows that each Lysolat is three to four times stronger than the same weight of any Lysol in existence, and is equal to six times its own weight of the finest carbolic acid.

Properties

Lysolats are made in the form of portable, non-corrosive tablets, each the equivalent of a standard half-teaspoon.

They are more readily soluble in water than any other solid antiseptic or disinfectant in existence.

Dissolved in alcohol, Lysolats give the quickest and most efficient sterilizing solution known to medical science. This solution in alcohol, when used as a dressing for scalds and burns, leaves the skin with an antiseptic surface, and is therefore rapidly superseding the lead lotion treatment.

Members of the Medical Profession are invited to write for free samples of Lysolats to Solidol Chemical Ltd., Asmead House, Disney Street, London, S.E.1.

Lysolats
PATENT 118667 (LYSOL TABLETS)

Lysolats are packed in handy tins containing 40 and 80 tablets (at 1/3 and 2/- respectively), and also in tins of 1,000 tablets.

Specially indicated in
NEPHRITIS—URÆMIA
ECLAMPSIA—ALBUMINURIA
and allied conditions

Prompt and proper diagnosis of kidney conditions is necessary in cases of Bright's disease and all types of renal disorders. In nine cases out of ten the administration of a specific capable of producing real results in compensating for the loss of kidney function is also necessary.

For more than a quarter of a century Nephritin has been a sheet anchor to physicians in treating such disorders. Nephritin Tablets induce a marked increase in nitrogenous waste elimination. They reactivate the cells of the kidney, increase urinary secretion, and induce a greater output of urea. Given in sufficient dosage these tablets produce marked results, and restoration to normal is quickly stimulated.

They are invaluable also as a prophylactic in renal complications of infectious diseases and during pregnancy.

The tablets are composed of the hormones of the normal kidney as they appear in nature—*absolutely unaltered.*

ALOCOL

Colloidal Hydroxide of Aluminium

Successful Treatment of Hyperchlorhydria

"Alocol" is a triumph of colloidal therapy, because it is completely free from the marked disadvantages associated with the usual alkaline medicaments.

Take bicarbonate of soda as an example. When in the stomach it is transformed into sodium chloride—the very product which goes to the formation of hydrochloric acid. To combat hyperacidity by such means is to create a vicious circle.

Note the different action of "Alocol." It absorbs excess of hydrochloric acid and the acid-containing mass is finally evacuated from the lower bowel. This colloido-chemical absorption removes from the system the causative acid radicle (Cl) instead of merely neutralizing it. "Alocol" thus prevents reabsorption, accumulation, and consequent recurrence of the symptoms of the disease.

"Alocol" leaves intact the acid reaction of the gastric juice and its normal digestive and bactericidal functions. It is the remedy *par excellence* for hyperchlorhydria. The absorbent, healing, and sedative properties of "Alocol" also prove of the greatest value in successful treatment of the more serious manifestations, such as gastrectasis, gastrelcosis, pyloric and duodenal ulcers, infective enteritis, etc.

Complete chemical history of "Alocol" with convincing clinical reports and supply for trial, sent free to physicians on request.

HOVIS

IRREFUTABLE EVIDENCE

Scientific Research into the essential factors underlying the bread question has brought to light certain facts of the highest practical value to medical men as well as to the general public.

HOVIS is shown, from an analysis of many experiments, not only to possess a larger content of the vital element Vitamin B than other breads, but provides more positive nourishment for the quantity consumed.

One slice of HOVIS weighing 1 oz. contains as much Vitamin as 2 oz. of wholemeal, or 5 to 6 g. of fresh yeast; white bread contains only about 2 per cent. of yeast.

It is also found that "brownness" of bread is no measure of the Vitamin content.

The Wheat Germ
the secret of Hovis Nutrition

By blending the finest white flour with 25 per cent. wheat germ, HOVIS combines the goodness of the one with the rich Vitamin B qualities of the other. Further, containing no bran, it is very easily digested.

These facts all point to one conclusion: that in dietetic value HOVIS holds the first place for promoting health.

NEW-PROMONTA

A SCIENTIFIC FOOD FOR THE NERVOUS SYSTEM

The main feature of "NEW-PROMONTA" is that it contains *Lipoids, Phosphatides and Vitamins absolutely unchanged and in the exact amount* necessary to stimulate cell metabolism.

"NEW-PROMONTA" is indicated in:

1. All forms of Neurasthenia.
2. In cases of Insomnia.
3. In various types of Anæmia.
4. After-effects of Influenza.
5. In conditions of Functional Insufficiency.
6. In Illness and in Convalescence.

It is pleasant to taste, and is readily assimilated.

What the Medical Profession says about New-Promonta

28.10.28.

"It may interest you to hear that I have found New-Promonta the finest preparation of its kind that I have ever tried."

Major R.A.M.C.

19.11.28.

"I have had the opportunity of testing your product out in three cases, all of which made rapid improvement:—

"**Case 1.**—Adult male suffering from neurasthenia of two years' duration. He had drifted from one doctor to another during that period, receiving various treatments. After the first few days' treatment with New-Promonta he stated that he felt 'an entirely new man,' and he continues to improve.

"**Case 2.**—Adolescent youth suffering from languor, anorexia, and anaemia. Since he has taken small morning and evening doses of your product he has improved steadily.

"**Case 3.**—Medical practitioner suffering from the mental and physical strain of the present influenzal epidemic. He states: 'Every dose of New-Promonta puts new life into me.'

"Personally I consider you have produced an excellent nerve tonic and will continue to prescribe it." M.B., Ch.B.

"We have given it a thorough trial and formed a high opinion of its efficacy. . . . . To those who have not yet used New-Promonta we strongly recommend it."

Journal of R.A.M.C., No. 1, Vol. LI, July, 1928.

16.11.28.

"I was very pleased with the results obtained, and have now ordered this preparation for the patients of this hospital."

M.D., Ch.B. F.R.F.P.S.

and many others.

New-Promonta is available in powder form in boxes of ¼ lb. at 3s. and ½ lb. at 5s. 6d., and in tablet form in boxes of 54 tablets at 3s. 6d.

It may be obtained from the leading Chemists and Stores.

Benger's Food—*the adjustable diet.*

The "LANCET" describes it as "Mr. Benger's admirable preparation."

Owing to the presence of the natural enzymes of digestion (*Amylopsin* and *Trypsin*), and its method of preparation for a patient, the extent of self-digestion of Benger's Food and the milk with which it is mixed *can be regulated to suit the digestive powers of the patient.*

Benger's Food is prepared with fresh cows' milk. It forms a dainty cream which becomes the easier of digestion the longer it is allowed to stand after mixing. The process may be arrested at any time by simply bringing the mixture to the boil. (A useful average time for standing is 15 minutes).

Patients ordinarily unable to digest milk can take this mixture satisfactorily, as the Benger's food so softens the casein that when under the influence of the gastric juice it forms into minute flocculi instead of a heavy curd.

Benger's Food is of the highest nutrient value and is not found to pall, even when taken over long periods.

A Physician's Sample will be sent post free to any member of the Medical Profession making application to the Proprietors—

The perfectly filled Toast Rack holds only "Ryvita Crispbread"

RYVITA CRISPBREAD — the wonderful daily bread of Sweden—is made of rye and nothing but rye, the only cereal from which the true "crispbread" can be made.

Many thousands of British doctors and dentists recommend "Ryvita" and use it in their own homes as a veritable bread of life and health.

The enthusiastic welcome and instant adoption of "Ryvita Crispbread" by food experts and the public has led to the astonishing success that has by now firmly established "The Ryvita Crispbread Habit" in our country.

"Ryvita," for every bread use, helps to make indigestion, constipation, malnutrition and obesity unknown. Yet . . . so unique is this wonderful bread that it is almost impossible, even when dieting, to eat too much of it.

Try "Ryvita" with butter and marmalade and you will discover an almost unbelievable improvement on your old time breakfast toast. "Ryvita" makes you fit and keeps you slim.

Sold by all good grocers and stores at 1/6 per (40-50 slice) 1-lb. carton; ½-lb. 10d.

RADIO-MALT

Radio-Malt is definitely anti-infective—a fact of special importance to all physicians, particularly at this time of the year.

Radio-Malt possesses also antirachitic, antineuritic and growth-promoting properties; it promotes normal dentition in the young, and it checks dental caries in the old and young alike; also it is definitely tonic in its action.

Radio-Malt is prepared and standardised by scientific methods which are recognised as sound. Being accurately-standardised—also more concentrated and, consequently, more intense in its effects—it is more reliable than malt and cod-liver oil, which it definitely supersedes.

There is no effective substitute for Radio-Malt.

Physician's sample will be sent on receipt of a professional card.

Nature's Remedy for Lack of Sunshine — Cod Liver Oil

Cod Liver Oil abounds in natural vitamins. It is a natural not an artificial food.

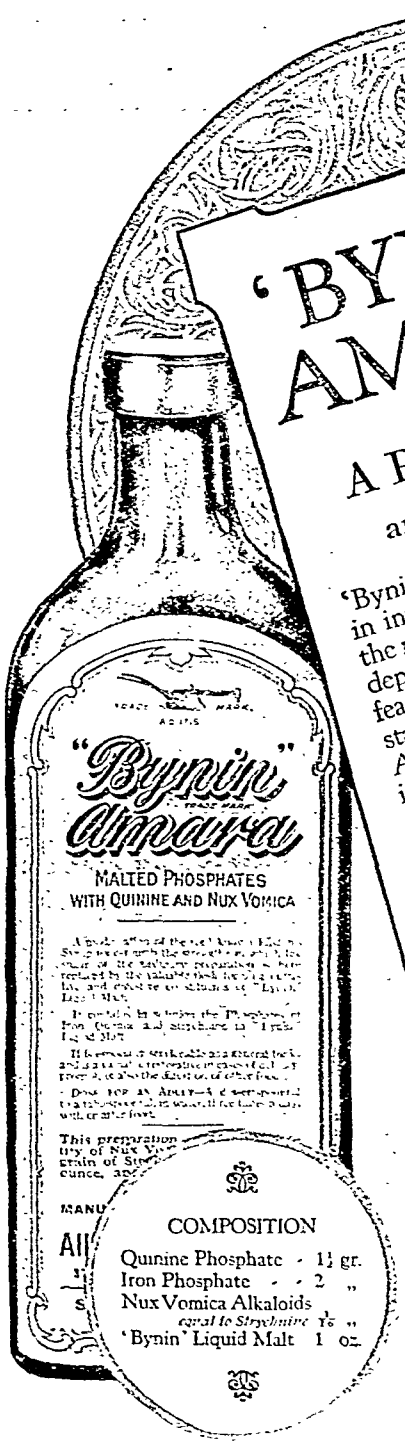
For centuries it has supplied the remedy for lack of sunshine and lack of Vitamins A and D. Long experience has proved its value.

Vitamin A is essential to sound growth and the maintenance of health. Vitamin D has one purpose only — it prevents and cures rickets in children. It is essential to the formation of healthy bones.

Cod Liver Oil supplies Vitamins A and D in a *natural* food which is easy to absorb because of its high percentage of glyceryl esters of unsaturated fatty acids.

NORWEGIAN COD LIVER OIL

FABRITIUS, OSLO.



'BYNIN' AMARA

(TRADE MARK)

A Powerful Tonic and Hæmatinic

'Bynin' Amara is of special value in influenzal conditions and in the marked asthenia and nervous depression which are prominent features of the post-influenzal state. A course of 'Bynin' Amara whenever there is any indication of lowered resistance is a valuable safeguard against infection.

It has important advantages over Easton's Syrup on account of its basis being 'Bynin' Liquid Malt in the place of syrup. The 'Bynin' Liquid Malt, besides having valuable digestive and nutritive qualities is an efficient solvent for the other ingredients and helps to mask their unpleasant taste.

In bottles at 3/6, 6/6 and 12/-

EXCEPTIONALLY FINE KELTIC HORSE-TRAPPINGS FROM BRITAIN, WHERE THE ART OF ENAMELLING REACHED ITS ZENITH.—The art of enamelling appears to have been introduced into Britain by the Keltic pioneer explorers. They continued to practise it with more and more skill until they produced specimens which far surpassed those of their continental kinsmen. In the example reproduced on the right the paler portions of the fine design are enamelled a rich red, the bronze having been scooped out to receive the enamel. By this time colours other than red had been introduced; the quatrefoil seen in our illustration on the left is of dark blue while the circular background is red. Green, yellow and white also were commonly employed. Luxury among the Kelts of this period took the form chiefly of magnificently engraved and enamelled armour for their warriors and harness for their horses; helmets, shields and horse-trappings remain to testify to this, the finest among them having been found in England.

VITAMINS A, B & D
HAVE ALWAYS BEEN IN CADBURY'S MILK CHOCOLATE.

Fresh milk only is used in Cadbury's Milk Chocolate, which is made by a distinctive process incorporating the fresh milk direct with the chocolate.

By this process, the important Vitamins A, B and D, natural to fresh milk, are retained.

Owing to its concentrated form (there are 1½ glasses of milk in every ½-lb. cake) the chocolate is appreciably richer in Vitamin D than milk itself. Further, it contains the whole of the bone-forming calcium and phosphates present in the milk. All the essentials of an anti-rachitic food are contained in Cadbury's Milk Chocolate.

The dietetic value of milk has always been recognised by the medical profession — a convenient and concentrated form is Cadbury's Milk Chocolate.

This chocolate is sold in 2d. Bars, 6d. Packets, and 1/- ½-lb Blocks.

Reminders and Suggestions

SYRUP CREOSAL (DUBOIS)

A combination of Guaiacol, Calcium, and Phosphoric Acid (Calcium Monoguaiaco-Phosphate) pleasantly flavoured with Syrup of Orange Flower and Cherry Laurel.

Remarks ON THE TREATMENT OF EMPYEMA.*

BY

F. G. THOMSON, M.A., M.D., F.R.C.P.,

PHYSICIAN, ROYAL UNITED HOSPITAL, BATH.

If we study the statistics of empyema we cannot help being impressed by the fact that it is a very serious disease. Thus, of 1,310 cases in the London Hospital in fifteen years (1909–23) the total mortality was 23.9 per cent.[1] Of 499 cases treated at St. Bartholomew's Hospital the mortality was 28.2 per cent. In infancy the disease is peculiarly fatal. Most observers agree that during the first year the mortality is about 75 per cent., and during the second to fourth year anything from 40 to 60 per cent. Holt puts the mortality during the first year as high as 90 per cent.[2] In older children and in young adult life the mortality is much less, 6 to 20 per cent., but in older people the figures rise again, the London Hospital figures being 31 per cent. at 40 to 50 years of age; 39.4 per cent. at 50 to 60; and 38.4 per cent. at 60 to 70.[3]

The percentage of deaths from empyema among soldiers in 1918–19 during the epidemic of influenza was appallingly heavy. The Surgeon-General's statistics in America showed the average mortality to be about 30 per cent., and in some of the military camps it rose as high as 70 per cent.

When we regard these extremely high figures of mortality, and when we consider, moreover, how many cases which recover for the time being are left with chronic empyema which renders them permanent invalids, and possibly leads to death some few years later, we cannot help wondering whether it should not be possible, by a better understanding of the principles of treatment, or the adoption of a more suitable technique, to obtain more satisfactory results than have hitherto been possible. As the result of the heavy mortality in the military camps in America in 1918, a special commission was set up to study this question, and certain definite principles were enunciated which, it was claimed, made an enormous difference in the results obtained.

Before going on to discuss methods of treatment I should like to remind you of certain facts concerning the physiology of respiration and the physics of pleural effusion and pneumothorax. In a normal healthy adult the average vital capacity—that is, the maximum amount of air that can be expired after a full inspiration—is about 3,700 c.cm. During ordinary quiet respiration, however, the amount of air taken in during each inspiratory effort, the so-called tidal air, is only about 500 c.cm.—rather less than one-seventh of the maximum vital capacity. In the case of a patient with a pleural effusion, or a closed pneumothorax, it follows that though the maximum vital capacity is diminished in proportion to the size of the effusion, the patient is able to carry on quite comfortably so long as he is at rest, provided the effusion is not large enough to prevent the inhalation of some 500 c.cm. of air during each inspiration. Directly he begins to move about, however, and the normal tidal air is not sufficient to provide for his increased need of oxygen, he becomes very short of breath.

Now the usual conception of the physics of a pleural effusion implies that the mediastinum, though subject to more or less displacement according to the size of the effusion, does, as a matter of fact, impose some barrier between the two sides of the chest, so that, although one side may be almost full of fluid and the lung almost entirely thrown out of action, the lung on the other side is able to carry on in virtue of being shut off by the mediastinum.

Now Dr. E. A. Graham[4] and the other members of the U.S.A. Empyema Commission appear to have proved by a series of experiments that this conception of the physics of pleural effusion is fundamentally wrong. By introducing a water manometer into each side of the pleura, both in animals, and in patients recently dead from diseases not affecting the thorax, Graham showed that injection of air into the pleura of one side affects the intrapleural pressure on the other side to an equal degree. By injecting the trachea with plaster-of-Paris and then removing the lungs he was also able to demonstrate that the density of the two lungs was equal. In other words, the compression induced in one lung by injection of air into the pleura on that side was accurately reflected in the compression induced in the lung on the contralateral side.

Now so long as we are dealing with a pleural effusion or a pneumothorax, in a closed chest, it is not a matter of very vital importance whether the mediastinum imposes an effective barrier between the two sides or not. So long as there is sufficient space left in the thorax for the patient to inhale some 500 c.cm. of air every time he breathes, it does not much matter whether he inhales it into one lung or both; but when we convert a closed pleural effusion into an open pneumothorax, which is what we virtually do when we treat an empyema by resection of a rib and open drainage, the question of the imposition of an effective barrier by the mediastinum between one side of the chest and the other becomes one of the utmost urgency. If at each effort of inspiration air is sucked into the pleural cavity by way of a large open drainage tube, at the same time as it is sucked into the lung by way of the trachea, the amount of air which enters the thorax by these two routes respectively is governed entirely by the resistance offered by the trachea and bronchial tubes on the one hand, and by the open drainage tube on the other; and if, as Graham asserts, and I think asserts truly, there is no effective barrier between one side of the chest and the other—if, in other words, we must regard the thorax as a single cavity and not as two separate cavities—it is possible, by increasing the size of the opening in the chest wall, to produce a condition in which all the air enters into the pleura and none into the lung. In other words, to produce sudden asphyxia and immediate death; and as a matter of fact this is what actually does happen, provided the opening in the thoracic wall is sufficiently large. Short of this it is found experimentally that an attempt is made, by means of forced respiratory efforts, to overcome the disability induced by the open pneumothorax. Inspiration becomes very much deeper, and results in partial compensation. The intrapleural pressure becomes negative during the height of inspiration, and so enables the animal to inhale a sufficiency of air to keep it alive. If the pneumothorax is temporarily closed the animal experiences immediate relief, and by the end of about five or six minutes the negative pressure in the pleura has attained its normal range during the whole respiratory cycle. Owing to the partial compensation effected by forced inspiration it is possible to sustain life with a much larger opening in the chest than would otherwise be the case, and Graham has worked it out on mathematical principles that the largest opening compatible with life in an average healthy adult man is about 8 sq. in. (2 in. by 4 in.).

In a patient suffering from empyema, however, the additional embarrassment of respiration produced by an open pneumothorax is a much more serious matter. One lung at least is partly thrown out of action by consolidation, and in streptococcal broncho-pneumonic cases both lungs are involved—and this at a time when more oxygen than normal is required to keep pace with the increased metabolism of fever. The muscles of forced inspiration have already been brought into play, and, owing to the patient's general toxaemia and weakness, they are in no condition to make any sustained effort of compensation to counteract the effects of an open pneumothorax. We can readily appreciate, therefore, that an open resection, followed by the introduction of a large drainage tube, in a patient already desperately ill, may easily give an adverse turn to the balance between life and death.

In order to test the effect of open drainage, Graham performed an interesting series of experiments on animals. After some difficulty he was able to isolate a strain of streptococci which produced empyema when injected into the pleura of dogs. Ten pairs of dogs, carefully graded as regards weight and general condition, were inoculated, and

* An address given to the Trowbridge Division of the British Medical Association, November, 1928.

twenty-four hours later a stiff open drainage tube, 1/4 in. in diameter, was inserted into the thorax of one of each pair. Of the ten drained dogs all died except one which tore out the tube, and was found later, when killed, to have had an empyema which had healed. Of the undrained dogs seven died, one as the result of injuries by fighting with another dog, and three recovered. When both dogs of a pair died, the one that had been drained died sooner than the other in every case. So far as they go, then, these experiments show that open drainage, instead of being of value, was attended by greater mortality and earlier death.

The statement that treatment of an empyema by open drainage imposes an additional handicap by further embarrassment of respiration only applies, of course, to cases in which there are no adhesions. In those patients in whom the empyema is sealed off from the rest of the thoracic cavity by dense adhesions between the visceral and parietal layers of the pleura it is a matter of little or no importance, as far as the physics of respiration are concerned, whether the cavity is closed or open, and whether it is filled with pus or atmospheric air.

It is necessary, therefore, to distinguish clearly between two classes of empyema—those in which the pus is lying free in the cavity of the thorax, and those in which it is shut off by adhesions. Now the formation of adhesions is entirely a matter of time. In cases of ordinary lobar pneumonia, where there is always a certain amount of pleurisy as well, an empyema is usually a comparatively late manifestation. It develops gradually as the pneumonia begins to subside, and by the time it is diagnosed it is usually cut off entirely from the rest of the thorax by the formation of thick masses of adhesive fibrin. On the other hand, in the case of streptococcal empyema associated with broncho-pneumonia the condition is just the reverse. The invasion of the pleura by infective organisms takes place quite early in the illness. An empyema develops almost at the same time as the broncho-pneumonic changes in the lung, and it may appear so rapidly as to constitute almost a primary manifestation of the illness. In such cases there has been no time for adhesions to form, and the empyema is lying perfectly free in the cavity of the thorax. Such cases, which are specially common in infancy, are always severe, and the patient, especially if a very young child, is usually desperately ill, and any elaborate or immediate operative intervention, especially if it involves even a temporary open pneumothorax, is much more likely to kill it than to save its life. If it is determined to apply open drainage at all to a case of this type it is absolutely essential to temporize, and to be content with aspiration, to evacuate the pus, till such time as adhesions have had time to form and seal off the cavity from the rest of the thorax. Aspiration itself is a somewhat painful and distressing procedure, and to perform with success a second or even a third aspiration on a desperately ill and probably terrified child is not necessarily as easy or satisfactory as it might at first sight appear. It is in such cases especially that the performance of continuous suction drainage, by the introduction of a soft self-retaining catheter attached to a water-pump, appears to offer such enormous advantages over other methods of treatment. The introduction of the catheter itself is a very trivial affair, and entails very much less shock than any more elaborate surgical intervention, and since it avoids the risk attached to the induction of an open pneumothorax this method may be employed at the earliest moment, even in streptococcal cases, in which no adhesions may be expected to have formed.

Whatever method is adopted to drain an empyema there is one important principle to be observed in the after-treatment, and that is the paramount necessity of sterilizing the cavity at the earliest possible moment and of preventing any secondary infection through the opening made in the chest.

Bacteriological examinations seem to show that secondary infection of the cavity during the period of drainage is largely responsible for delay in the recovery of a great many patients. Prolonged inflammation of the pleura, whether it results from the primary infecting organism or from some secondary infection, causes the ordinary endothelium of the pleura to be replaced by fibrous connective tissue, with the result that the lung is firmly bound down and prevented, possibly for ever, from completely expanding to fill up the chest. A permanent thick-walled cavity may thus be formed, and a chronic empyema result, with all its attendant risks to health and even to life. The sooner, therefore, that we are able to disinfect the cavity in the thorax, and the more successful we are in preventing the introduction of fresh organisms from without, the more likely we are to prevent the formation of a chronic empyema.

As a general principle, therefore, it may be said that an empyema cavity should be rendered sterile at the earliest opportunity, and in order to do this, frequent irrigation with some suitable antiseptic is of very great assistance. Of all antiseptics chlorine solution seems to be the most efficient and suitable. During the last two years of the war, when I was chiefly concerned with the treatment of some hundreds of patients with penetrating and, in many cases, heavily infected chest wounds, I found, in common with others, that frequent irrigation with Dakin's solution was of the utmost value. In the first place, it is non-toxic, and can be freely used without any fear of ill effects; and, secondly, it appears to have a special action in softening and breaking down those large masses of fibrinous exudate which so often make efficient drainage a matter of great difficulty.

There is one point in connexion with the disinfection of an empyema cavity that is of some practical importance, and that is, that the upper part of the cavity seems less easy to render sterile than the lower part. This is probably because the rounded surfaces of the lower part of the cavity are more accessible to the antiseptic than the narrow sinus between the expanding surface of the lung and the upper part of the chest wall. Whatever the explanation may be, it is found in practice that it is more satisfactory to make the opening in the chest wall near the upper limit of the cavity rather than, as one would naturally expect, at the most dependent part.

Though I have directed my remarks chiefly to the principles which it appears ought to be observed if the treatment of empyema is to be satisfactorily carried out, I may perhaps be allowed to make a few remarks about the methods by which these principles would appear to me to be best put into practice. Before doing so, however, it may be as well to recapitulate shortly what those principles are. The principles to which any ideal form of treatment should conform are:

1. Operative procedure should be such as involves the minimum of time and the minimum of shock.
2. If it is necessary to employ the method of open drainage, this should never be performed until it is reasonably certain that the empyema cavity has become sealed off from the rest of the thorax by adhesions.
3. In connexion with the last it is imperative to distinguish between pneumococcal empyema, in which adhesions are usually formed by the time the empyema is diagnosed, and streptococcal empyema, where adhesions are not usually formed till later.
4. In order to minimize the risk of secondary infection the opening in the chest wall should be no larger than is sufficient to admit a suitable drainage tube, and should fit closely around the tube when it is placed in position.
5. The cavity should be sterilized as early as possible by frequent irrigation with some suitable antiseptic, to prevent the formation of dense fibrous adhesions, which prevent the expansion of the lung and the early closure of the cavity.
6. The lung should be encouraged to expand by ensuring a negative pressure in the pleural cavity throughout the period of drainage.
7. Convalescence should be assisted by giving plenty of nourishing food, and, whenever possible, by treating the patient entirely in the open air.

The method of treatment which would appear to fulfil these principles more completely than any other is that of closed continuous-suction drainage. This method is, of course, by no means new. It has been tried by various people and in different hospitals for a good many years. For certain reasons, however, it does not seem to have attained that measure of popularity which I venture to think it deserves. The technique usually employed, of introducing a stretched rubber tube through a metal cannula, which is allowed to remain in position, presents

a very real disadvantage in the fact that the cannula is very apt to become displaced, especially in a restless child, and come out of the chest, pulling the drainage tube with it. This difficulty is entirely obviated by using a self-retaining rubber catheter, which is either introduced direct through a very small incision into the chest, or through a cannula, which is withdrawn immediately the drainage tube has been inserted. I have had an oval trocar and cannula specially made to enable a larger catheter to be introduced between the ribs than would otherwise be possible, but I am not sure that this method presents any material advantage over the method of direct introduction through a small incision in the chest wall. Two other disadvantages have been cited against this form of treatment—namely, that it is difficult to ensure adequate drainage, and that after-treatment requires almost continuous supervision by specially trained nurses. With regard to efficiency of drainage, we have not found the difficulties so great as would be thought. Irrigation of the cavity by Dakin's solution, two or three times a day, seems to soften or disintegrate those large masses of fibrin which so often impede the free passage through the tube. If the latter appears to be blocked it is detached from the suction apparatus, and, by means of a glass syringe, Dakin's solution is alternately forced gently through the tube and sucked out again. By doing this a large amount of fibrin can often be removed, and when the suction apparatus is replaced drainage is found to proceed quite satisfactorily. The last objection to continuous suction, that it requires unremitting attention, is only partially true. Once it is satisfactorily started very little attention is required, unless the tube gets blocked and requires syringing out, as it occasionally does. Irrigation with Dakin's or some other antiseptic ought to be carried out at least two or three times a day, no matter what method of drainage is adopted, and it is much easier to detach the suction pump and irrigate through the catheter than it is to remove the messy dressings from a patient's chest and irrigate through an ordinary open tube. One way and another, I do not think that this method requires more attention than can easily be given in the ordinary routine way in a hospital ward or a nursing home.

During the last eighteen months I have treated all cases of empyema coming under my care, twelve in all, by this method. Of these twelve cases, one, a man of 35, who had a large chronic empyema of some five months' duration, died as the result of multiple cerebral abscesses three weeks after admission, and while the empyema was still draining. The other eleven cases have all done uniformly well.

After removal of the catheter I have, in all cases, put a fine tube into the sinus to drain the small cavity remaining. The sinus is usually healed completely after three or four days, but in four of my patients the wound, after closing up, has broken down again, and a small abscess has discharged, after which the sinus has again closed up and given no further trouble. This is perhaps due to the wall of the sinus itself being infected, and can probably be obviated by treating the latter with flavine or some similar preparation. In all cases except one the cure has, I believe, been complete, and, so far as one can tell, permanent. One patient, who originally had a very large staphylococcal empyema of ten weeks' duration, returned to his work as a miner some six weeks after discharge, and came back to hospital two months later with an abscess pointing over the old sinus; some six ounces of pus were evacuated from the cavity, which rapidly healed and has not, so far, recurred. Another patient had a double empyema, both sides being drained simultaneously, and closing on the seventeenth and eighteenth days respectively. This patient has remained fit ever since, and I am informed he has been for some months working about his farm as usual.

The average period during which drainage has been required has been nineteen days. One particularly satisfactory feature in all has been the rapid expansion of the lung, as shown by the amplitude of respiratory movements on the affected side, and the return of breath sounds at the base.

The ages of the eleven patients still living ranged from 4 to 50 years; the organism isolated was the pneumococcus in eight cases, combined in one instance with the streptococcus and the tubercle bacillus; in two cases the staphylococcus; and in one case the *Bacillus coli*.

The advantages that I think one can justly claim for treatment by continuous suction drainage are:

1. Introduction of the catheter is rapid and easy, and entails virtually no shock.
2. Anaesthesia is correspondingly brief, and, if necessary, the operation could be done, except perhaps in infants, with a local injection of novocain.
3. The tube causes little or no pain.
4. Nursing of the patient is much easier and cleaner.
5. The risk of secondary infection of the empyema is very much diminished.
6. The wound closes quicker than by open drainage.
7. Re-expansion of the lung is more rapid and complete.

THE PROGNOSIS AND TREATMENT OF ECLAMPSIA AND ALBUMINURIA:

WITH SPECIAL REFERENCE TO THE RISK OF RECURRENCE IN SUBSEQUENT PREGNANCIES.*

BY

JAMES YOUNG, D.S.O., M.D., F.R.C.S.ED.,

PHYSICIAN, EDINBURGH ROYAL MATERNITY AND SIMPSON MEMORIAL HOSPITAL; GYNAECOLOGIST, ROYAL INFIRMARY, EDINBURGH.

IT is in some ways remarkable that, despite the close study which the clinical features of the toxaemias of late pregnancy have received, we should now be discovering, not only that there are still a few fields left for us to explore, but that some of our teaching on the basic clinical facts has proved to be incomplete and in certain respects actually unsound. Take, for example, eclampsia. It has been almost a commonplace in our teaching that a woman who has suffered from this condition is little likely to suffer in any similar way in her next pregnancies. A study of such cases proves this to be incorrect. At the British Congress of Obstetrics and Gynaecology in 1927 I[1] showed that in 47 consecutive cases of eclampsia in parous women admitted to the Edinburgh Royal Maternity Hospital eclampsia occurred six times in a previous pregnancy and "albuminuria" nine times. This gave a total recurrence figure of 31.9 per cent. Adding to this six cases, in which there had been abortion, accidental haemorrhage, premature or stillbirth without toxaemia in the previous gestations, we got a total recurrence of abnormality of 44.7 per cent.

Dr. Jessie C. B. Sym has since carried out a similar investigation of the subsequent obstetric history of the surviving cases of eclampsia treated in the hospital from 1919 to 1926, and in a total of 67 cases which were traced she found that 42 had become pregnant again, with a total of 60 completed gestations. Of these, 3 had developed eclampsia for the second time, with a fatal result in one case, whilst in 15 of the other pregnancies "albuminuria" occurred, giving a total of 18 out of 60 subsequent pregnancies which were toxaemic, or 30 per cent. Adding to this 6 more, in which abortion, etc., took place, we get 24 abnormal pregnancies out of a total of 60, or 40 per cent., a figure which emphasizes the risk which is run by an eclamptic patient should she become pregnant again.

A similarly sinister record is revealed when the "albuminuria" cases are studied. In the paper to which I have already referred I recorded a recurrence of toxaemia, and of abortion, etc., without toxaemia, in 42 out of a total of 118 studied—that is, in 35.6 per cent. These figures referred to the previous pregnancies in parous women admitted to the hospital with "albuminuria." By following the surviving cases into their subsequent obstetric life we have found that 51 out of 81 cases subsequently became pregnant again, and had between them 84 completed pregnancies. Of these, 44 had "albuminuria" (this diagnosis was based on clinical evidence supplied by the patient in 5) —that is, 52 per cent. In 14 of the other pregnancies there occurred abortion, accidental haemorrhage, etc.,

* A paper read before the Section of Obstetrics of the Royal Society of Medicine, November 16th, 1928.

without toxaemia, making a total abnormality recurrence of 58 in 84, or 69 per cent. The considerable increase in the percentage of recurrence in the pregnancies occurring after the first toxic gestation treated in hospital as compared with those in the pregnancies prior to this is to be accounted for by the fact that in many instances the follow-up proved the attack of toxaemia treated in the hospital to be the beginning of the recurring sequence.

We thus see that 82 out of a total of 144 subsequent pregnancies in cases of toxaemia (eclampsia and "albuminuria") were vitiated by toxaemia or intrauterine disaster to the foetus without toxaemia—that is, a percentage of 57. Furthermore, 3 of the 93 women who became pregnant subsequent to their leaving hospital died from toxaemia in a subsequent pregnancy—that is, more than 3 per cent. It is probable that this death rate would have been actually higher could all the cases have been followed up, for it is known that "deaths" are notoriously difficult to trace.

Findings similar to those here recorded have been reported by other observers—by Greenhill[1] and Gibberd,[2] for example. Greenhill studied the subsequent completed pregnancies of 16 women who had had eclampsia, and found that in 9 these were normal, whilst in 7 they were toxaemic—that is, in 43 per cent. Gibberd found that in 26 cases of albuminuria there was a recurrence of the toxaemia in 19—that is, 68 per cent.

This large incidence of recurrence in all classes of toxaemia carries with it implications of far-reaching importance. In my opinion this fact of recurrence, applying as it does to all types of the disease—eclampsia, pre-eclampsia, etc.—constitutes the most significant addition to our knowledge of the subject made within recent years, and it must be regarded as an important new clue in our efforts to trace the underlying causes.

The first lesson it teaches is the inadequacy of our present classification, for this has been based on the view that eclampsia and "pre-eclampsia" are essentially non-recurrent. The type in which recurrence is the characteristic feature we have thrown into a category by itself. We have classed it as "recurrent," or, in view of the observable kidney lesion sometimes accompanying it, as "nephritic." The new discoveries obviously render this classification unsound, for it is clear that in respect of the criterion of recurrence there is nothing to distinguish one kind of late pregnancy toxaemia from another. Furthermore, it is apparent that the view which attributes recurrence to a defect in renal function must, if well founded, apply equally over the whole range of these toxaemias.

I have elsewhere discussed the discrepancies in fact and in theory which seem to me to lie at the back of any such view, and I cannot enter into the matter fully on this occasion. At the outset I would direct your attention specially to the fact that the attitude we adopt towards this question has implications which are not merely academic in their nature. Bound up with them are important issues of an essentially practical nature. We may, in the first place, in accordance with the usual teaching, attribute the tendency to recurrence to a chronic renal defect, which leads to a breakdown of function in succeeding pregnancies. In support of this view we may cite the nephritis which punctuates these recurring toxaemic gestations, and, in addition, the evidence of nephritis which is sometimes found in the intervals between the pregnancies. On the other hand, we may regard the nephritis as caused by the toxaemia, which in such women tends to recur during their pregnancies, and the accumulated result of which in some instances may be to produce persisting and chronic nephritis. These two standpoints are distinct and mutually exclusive. According to one the recurring toxaemia springs from the kidney defect. According to the other the kidney defect springs from the recurring toxaemia.

For many years I have been unable to satisfy myself that in endowing the kidney with ætiological properties of a primary character we were not theorizing beyond our facts. As I now see it I am satisfied that, whilst we are still far from a complete understanding of all the phenomena, the data, when fairly marshalled and analysed, drive us in a very compelling manner to regard the kidney as an organ which in the sequence of events plays a part which is entirely secondary, and which in its liability to suffer damage by the specific toxins elaborated during the development of a vitiated pregnancy is in no way different from such other organs as the liver and the heart. The arguments in favour of this view may be summarized as follows.

1. A recurrent attack of eclampsia or albuminuria is in no essential fact different from the initial attack in the first pregnancy involved. Now there is no evidence that this initial attack is in any way, directly or indirectly, dependent upon a renal defect. There is, on the other hand, ample evidence that the kidney damage invariably occurring in such a case is directly caused by the toxins elaborated in a specific manner in some other region of the pregnant organism. Why in a recurrent attack should the relation of the kidney in the sequence be different?

2. Just as the initial eclampsia or albuminuria occurs typically in a woman whose kidneys were previously healthy, so typically in the intervals between the pregnancies, which are recurrently toxic, the kidneys reveal no evidence of any deficiency. Furthermore, subsequent to a series of toxaemic pregnancies, in each of which the kidneys have suffered, the patient may enjoy good health with no cardio-vascular or renal disease so long as she does not again become pregnant.

3. The chronic renal lesion found occasionally in such women is easily explained as due to the effects of one bad attack or to the accumulated results of the damage sustained during a recurrent series of toxic pregnancies. Dr. Jessie Sym has carried out an examination of the cardio-vascular system, of the blood urea and the urea concentration test, in 66 post-eclamptic and 73 post-albuminuric cases treated in the Edinburgh Royal Maternity Hospital. This revealed evidence justifying a diagnosis of chronic renal change in 2 of the post-eclamptic cases (3 per cent.) and in 6 of the post-albuminuric cases (8 per cent.). The significant fact is that in 7 out of these 8 cases the patients had two or more toxic pregnancies. Of those cases—comprising approximately half of the total number—in which a single toxic pregnancy had occurred, in only one was chronic renal change found, and in this case the toxaemia lasted for eighteen weeks. These facts indicate that the degree of involvement of the kidney is directly related to the interval over which it is exposed to the toxins of an abnormal pregnancy.

4. Marching side by side with the tendency to recurrent toxaemia there is a well-recognized tendency to the succeeding pregnancies of such women being terminated prematurely by abortion, stillbirth, or accidental haemorrhage. This tendency has usually been attributed to a chronic renal deficiency. In my previous papers I have called attention to the fact that these abortions, etc., may be unassociated with any toxic manifestations or any recognizable renal defect, although they occur in women known to have this tendency to recurrent toxaemia in their other pregnancies.

For lack of a better explanation in the past we have in similar contingencies had recourse to the "nephritic" conception. In this view these damaged pregnancies would be attributed to a deficiency in renal function which is so meagre that it fails to reveal itself in the ordinary ways. How, it may be asked, could such a minimal defect, which is insufficient to cause any clinical evidence of its presence, precipitate the intrauterine disasters which these crises necessarily imply?

It was considerations of this order that led me some years ago to approach these problems from a new angle. A critical analysis of the available data early proved that whilst the fact of toxaemia was the dominating clinical phenomenon, and as such had naturally obtruded itself into the forefront of the problem, it was by no means invariable and essential. It was rather of the nature of an accident or incident, which might occur in some circumstances but not in others. Thus, for example, it might be present in one pregnancy ending in accidental haemorrhage, whilst in the same woman it might be absent in the next pregnancy which ended similarly. Whilst toxaemia was thus purely incidental, there was, on the other hand, one factor, and one factor alone, which seemed to run

throughout the process as an invariable accompaniment of the abnormal pregnancies, toxic and non-toxic alike. This was disease of the placenta. In all the affected pregnancies, whether they ended by abortion, accidental haemorrhage, or stillbirth, and whether they ended in toxaemia or not, one could always find placental damage. The existence of such a pronounced lesion, which, according to this reading, must be considered as arising independently of the toxic process, naturally pointed to a possible source of the toxic elements, which all agree to be responsible for the toxaemia of pregnancy. As I have shown, it is possible to account for all the known facts by predicating in such women the existence of some factor which during pregnancy may precipitate a toxaemia by involving the life of the placenta. This factor, whatever it be, is liable to persist in the intervals between the pregnancies, during which it may cause no apparent trouble, but it is apt to reassert itself in the same way during the next pregnancy. Whether, after the placental damage has occurred, toxaemia will follow will depend on two variables: (1) the amount of placental tissue involved, and (2) the time during which the damaged placenta is retained in the uterus.

OBSERVATIONS ON TREATMENT AND PREVENTION.

From this study of the subsequent fate of toxaemic cases we may draw lessons regarding (*a*) the management of, and the indications for terminating, an existing pregnancy, and (*b*) the question of future pregnancies.

Management of Existing Pregnancy.

In every toxaemic case the immediate outlook is uncertain, and, even in the mildest case, it is impossible completely to exclude the risk that at any moment the clinical picture may change rapidly for the worse. For these reasons, were we to consult the interests of the mother alone, we would be justified in terminating the pregnancy in almost every instance so soon as the first toxic manifestations appear. In addition to these immediate dangers there is the more remote risk of the patient suffering lasting damage to her cardio-vascular system and kidneys. In this series of hospital cases, which, of course, comprise those suffering most severely, this risk assumes the proportion of 8 per cent. of the total. As I have previously shown it is minimal in the woman with her first attack, the major danger being reserved for those with repeated toxic pregnancies.

Against these sombre admissions there must be urged the experience of all that many toxaemic pregnancies respond with rapidity to ante-natal care and hygiene, with special reference to the diet, the bowels, and rest. It is in this class of work that modern ante-natal treatment has claimed some of its greatest triumphs. At the same time there is, it seems to me, a risk that we may overestimate our powers in this connexion, for we must acknowledge that in this disease, which affects 3.5 per cent. of all pregnant women (Eden and Holland), the majority of the cases are destined from the beginning to pursue a simple course, just as we know that the greater proportion of the severe cases resist all our efforts to cure them.

The only sanction we have for an expectant line of treatment is that we may thereby carry the pregnancy over into a period that will ensure the viability of the child. In this very matter, however, our decisions are still further complicated by the fact that the disease, which so heavily prejudices the life and health of the mother, is even more unkind to the foetus. Of all the maternal diseases toxaemia is the one which is most lethal to the child. Thus Holland, in a series of 301 foetal deaths, showed that 77 were caused by albuminuria, eclampsia, or accidental haemorrhage—that is, 26 per cent. In the present record of albuminuric cases 49 out of 168 children died *in utero*—that is, 29 per cent. It is known that many of those born alive survive only a short time.

These considerations show that whenever we elect to treat a toxaemic patient expectantly we may be gambling with the life or health of the mother in the interests of a child whose survival is problematical. I am convinced that in the past we have often been over-zealous in our regard for the child and too little attentive to the interest of the mother.

Where and whilst the manifestations are slight and the patient is under adequate supervision one may often safely temporize. In such a case, however, the termination of pregnancy as soon as the eighth month is well entered upon may be in the best interests of the infant.

Where there is marked oedema of the limbs and face, a blood pressure raised 30 or 40 mm. or more, a heavy deposit of albumin in the urine, a marked drop in the urinary secretion, and more especially if there are headache and visual symptoms, delay is dangerous. In less severe cases a delay sufficiently long to test the response to treatment may be considered justifiable, but any change for the worse, such as a rising blood pressure, a sudden drop in the quantity of urine, severe headache, etc., or a refusal of the symptoms to abate under rest in bed, watery diet, and active eliminative treatment, indicates the need for intervention.

In all toxaemic cases, except those that are mild, which are seen before the seventh month, experience has taught me that delay is rarely if ever justified, for this necessarily implies a dangerously long interval of waiting before viability of the child is reached. I would like to see it laid down as an axiom that, except in mild cases, no toxic patient should ever be kept under treatment for more than two weeks, and then only if the progress is good. A disregard of this precept may damage a woman's health irreparably; these risks, as we have seen, are especially to be guarded against in women who have suffered damage in their previous pregnancies.

For ordinary routine purposes, where the urgency is not immediate, the best means for the induction of premature labour is the gum-elastic bougie or some similar method. Pituitary extract is of little avail for this purpose until the last days of pregnancy, although the hypodermic administration of 5-minim doses of this drug is of value in reinforcing the action of the bougies once uterine efforts commence. I then use 5 minims every half-hour till a total of 2 c.cm. has been administered. Where the blood pressure is high, pitocin, which contains the ecbolic principle of the posterior lobe without the pressor agent, may be employed.

For cases of grave urgency the bougie method for inducing labour is too slow and too uncertain, and for such cases I employ Caesarean section under spinal anaesthesia. With this operation we obtain immediate evacuation of the uterus in a case where every hour's delay may jeopardize the prospects. By means of spinal anaesthesia we reduce the shock and we eliminate the risk of further damage to the organs associated with a general anaesthetic. Among these risks one of the greatest is irritation of the bronchioles, passing on to bronchitis and bronchopneumonia, from which toxaemic cases are specially liable to suffer.

For these reasons I have come to regard spinal anaesthesia as the ideal method in such cases. The immediate fall in blood pressure attending its use may in some ways be regarded as an added advantage in patients in whom an elevated pressure often constitutes a dangerous feature. At the same time I should like to take this opportunity of commending a wider employment of spinal anaesthesia as the routine procedure in Caesarean section. One of the most striking effects of the removal of the control of the spinal centres resulting from its use is a spontaneous and immediate contraction of the muscle of the uterine wound, producing a sort of natural haemostasis, which in many cases is so marked that the operation can be carried out literally without the loss of more than a few drachms of blood. In many instances—for example, in collapse from the exhaustion of a protracted labour or from loss of blood, as in placenta praevia—this fact may lead to a considerable reduction in the risk associated with the management of the case. A series of about 40 cases of Caesarean section so carried out by myself and my assistant with no mortality and in which are included a considerable number of grave cases of toxaemia, of placenta praevia, and of obstructed labour with potential sepsis, has led me to conclude that spinal anaesthesia has brought into the operation of Caesarean section a measure of safety which it

did not possess before. In cases where a drop in blood pressure is to be feared—as, for example, in the collapse from haemorrhage or in bad cardiac cases—I have, in addition, employed adrenaline, and, latterly, vasopressin.

At this point I would make it clear that once the toxaemia passes over into an eclamptic seizure any active intervention is to be rigidly avoided, and the patient must be treated along such lines of expectancy as those laid down by Stroganoff and others. On two occasions, it is true, I have carried out Caesarean section under spinal anaesthesia where the patients made a good immediate recovery under the Stroganoff treatment, but where, several days afterwards, there was a sudden and alarming recrudescence of the clinical features—rise in blood pressure, fall in urinary secretion, etc. The operative delivery was carried out with the idea that the risk of delay was greater than the risk of terminating the labour with the help of the spinal anaesthesia. A further indication in these cases was the continued intrauterine survival of the child, which I regard as a feature adding greatly to the gravity of the prognosis.

The Question of Future Pregnancies.

Among the lessons to be drawn from the data assembled in an earlier part of this paper there is one which is of profound importance. It is that the risk of toxaemia in subsequent pregnancies is so great that all such women should be warned of the importance of placing themselves under medical supervision from the early stages, should they again become pregnant. In the present state of our knowledge on ultimate causation we are not equipped with any certain method of protecting a woman with this taint against the risk of recurrence, but we can do much to safeguard life and health by emphasizing the imperative need of this ante-natal care if the major risks are to be avoided. The necessity for explaining these facts is all the greater because of the rapid recovery which usually follows on one attack and which often gives the patient a sense of security which is little justified. The woman who has already suffered from several toxaemic pregnancies should be the object of very special ante-natal supervision in the event of a future pregnancy.

The next point we have to consider is the advice to be given in regard to preventives. So great is the risk run by women with this taint that this matter of prevention may be considered as arising in practically all cases. Personally I believe it may be laid down as a rule that no woman should be exposed to further risk if she has had two or more toxic pregnancies, for the risk of future recurrence rises rapidly with the number of pregnancies already so vitiated. Where, on the other hand, the disease has involved the loss of the child on each occasion, there may be such a desire for a further attempt that the medical attendant may require to be satisfied with urging that this can only be sanctioned if the patient adequately recognizes the need for supervision throughout the pregnancy.

In anticipation of a future pregnancy everything should be done to build up the strength of the patient and to remove any factors that may, even indirectly, have a bearing on this tendency to recurring trouble. It has been suggested by some observers that focal sepsis may play a contributory part in the taint which these women carry over from pregnancy to pregnancy. In a previous paper I have referred to some considerations which are in keeping with this view, and have suggested that it is conceivable that some such factor is at the back of the tendency to placental disease, which, as I have pointed out, is the only essential lesion of the pregnancy in such cases. In a few instances I have found that, following the removal of gross sources of focal sepsis—for example, tonsils and teeth—a previously unbroken sequence of damaged pregnancies has been interrupted and has been succeeded by normal gestations. The data are still too meagre to allow of a definite pronouncement on this matter, and I merely throw out the suggestion tentatively. In eliminating this factor of potential sepsis, however, we are taking a step likely to help the general health and resistance even should the subsequent history fail to establish it as a factor of primary value.

Conclusions.

1. In a series of hospital cases treated for eclampsia and albuminuria there was found to be a recurrence of toxaemia or non-toxaemic interruption of pregnancy (abortion, accidental haemorrhage, etc.) in succeeding gestations in over 50 per cent.

2. There is no evidence that this tendency to recurrence is directly or indirectly dependent upon any persisting renal defect. Chronic nephritis is found in only a small proportion of cases, and there is evidence that this is the result of the toxaemia.

3. In view of the large risk of recurrence the need for ante-natal supervision from an early stage in the event of a subsequent pregnancy should be clearly explained to the patient.

4. Toxaemia in two or more pregnancies is an indication for the prevention of any further pregnancy.

THE PRESENT POSITION OF ULTRA-VIOLET LIGHT THERAPY.*

BY

C. B. HEALD, C.B.E., M.D., M.R.C.P.,

PHYSICIAN IN CHARGE OF ELECTRICAL DEPARTMENT, ROYAL FREE HOSPITAL; CONSULTANT IN ELECTRO-THERAPEUTICS TO THE R.A.F.M.S.

It is now so generally realized that ultra-violet light radiations consist of a small block of waves in the electro-magnetic spectrum that it is unnecessary to enter at any length into the physical nature of this source of energy. It is also realized that this electro-magnetic spectrum stretches from beyond the gamma rays of radium through x rays on to ultra-violet light, then through the visible spectrum to infra-red, and on to the Hertzian waves, which are employed both in wireless and in diathermy.

Owing to the extreme differences in wave-lengths between one end of the spectrum and the other, it has been found impossible to use the same unit of wave-length measurement, and this has constituted one of the difficulties in understanding the nature of ultra-violet light. The Angström unit is nothing more or less than an agreed subdivision of the metre or millimetre which gives a number to the shorter waves of the spectrum that is neither absurdly large nor carried to an absurd number of decimals. For instance, it would be extremely inconvenient to think or talk of the distance between Edinburgh and London as being, say, six thousand million million Angström units; and it would be equally inconvenient to talk of a hair having a diameter of, say, point seven or eight noughts one of a kilometre.

The Angström unit has, therefore, an arbitrary length of one ten thousand millionth part of a metre—that is, one ten millionth part of a millimetre. This arbitrary length enables us to talk of gamma rays in terms of tenths and hundredths of this unit; of x rays in tenths and small units; of ultra-violet light in figures round about three thousand, and of light up to about seven thousand. It is only when we get to infra-red that the numbers begin to get so big that it is worth while changing over from these units to actual millimetres or decimals of a millimetre. Thereafter, by keeping to the ordinary metric measurements, we eventually reach the well-known wave-lengths of 2 LO and 5 GB, and it is these latter wave-lengths that are employed in diathermy.

The relationship between the length of a wave and the frequency, or number of complete waves that can pass a given point in one second, can be made clear by a simple analogy. Suppose one is standing on a bridge watching a train composed of sleeping cars and ordinary cars passing underneath. The complete train will be travelling at a uniform rate, just as ether waves travel at a uniform rate, but the more lengthy sleeping cars will take a longer

* A lecture given to the Border Counties Branch of the British Medical Association.

time to emerge from under the bridge than the shorter ordinary cars. The sleeping cars would therefore have a longer "wave-length" and a lower "frequency," and the ordinary cars a shorter "wave-length" and greater "frequency."

The particles of dust on the surface of the cars would emerge, in comparison with the sleeping cars, at a very high frequency, but even then their frequency, in comparison with that of the sleeping cars, would not be as great as the differences between the frequency of gamma rays and those of wireless waves. It has been estimated that if the whole spectrum were set out to a scale in which one wave in the ultra-violet light block of waves was represented by one foot, and the whole block, therefore, by about 300 yards, it would be necessary to have a scale of more than one million miles in length. These facts give some idea of the minute proportion of the electro-magnetic spectrum that has produced such world-wide interest.

Apparatus for Making Ultra-violet Light.

In the course of a year I am frequently asked which is the best ultra-violet light lamp to buy. This question is impossible to answer without knowing all the circumstances under which the lamp is most likely to be used.

The common sources of ultra-violet light are:

1. The carbon arc.
2. The tungsten arc.
3. The mercury vapour arc.
4. Variations and combinations of 1 and 2, and arcs involving the use of other metals.

Each of these sources has its advocates, but I am of opinion that each has its own fields of utility, and I would not consider a department well equipped unless it contained representatives of at least 1, 2, and 3.

When arranging for the installation of one or more sources of ultra-violet light it is important, for the purposes of satisfactory and controlled work, that each lamp should have its own voltmeter and ammeter, so that the quantity of energy supplied can be kept fairly constant, or intelligently altered.

The carbon arcs are manufactured in various types, the commonest being:

(*a*) The 20-ampere arc lamps; three of these can, with a suitable main supply, be used in series if desired.
(*b*) The 75-ampere arc lamp.
(*c*) The Eidinow 30-ampere flame arc.
(*d*) The Finsen-Reyn lupus lamp.

Practically all the tungsten arcs rely upon swaged tungsten sticks, and only vary in such mechanical details as methods of adjusting the arc, reflectors, stands, etc.

The mercury vapour lamps, besides varying in detail as to the methods of cooling, are manufactured in five important types:

(*a*) The Cooper-Hewitt vacuum type.
(*b*) The atmospheric type.
(*c*) The Jesionek type.
(*d*) The Kromayer water-cooled type.
(*e*) A type suitable for use with an alternating current.

Each class of lamp has certain advantages and disadvantages, and these may be set out in tabular form.

1. Carbon Arcs.

Advantages.	Disadvantages.
1. Suitable for giving multiple treatments.	1. The 75-ampere type requires special motor. Current consumption great.
2. Function automatically and with little attention for long periods.	2. Tend to spit, splutter, make noises, and are affected by any draught.
3. Accidental overdoses produce less malaise than other types.	3. Smoke and smell somewhat, and carbon stick dirty.
4. Generate reasonable amount of heat at same time.	4. Slow in treatment.

2. Tungsten Arcs.

Advantages.	Disadvantages.
1. Consume only small quantity of current.	1. Much smoke and smell.
2. Simple in action.	2. Arcs require continuous watching and adjustment.
3. Rapid in treatment.	3. If much used, deposit a fine white dust over everything.
4. Rich in short wave-lengths.	4. Expense of tungsten sticks—5s. per inch (approximately).
5. Portable to patients, not difficult to use, and cheap.	

3. Mercury Vapour Lamps.

Advantages.	Disadvantages.
1. Consume only a small quantity of current.	1. Broken very easily; cost £10 to replace, and the vacuum type is liable to deteriorate.
2. Simple in action.	2. Work only when in one position—that is, the burner cannot be tipped.
3. Rapid in treatment.	
4. Rich in short wave-lengths.	
5. Clean and pleasant to use and almost inodorous.	

The above notes on the various types of lamp are extracted practically verbatim from a lecture I first gave some three years ago, and on looking through them I find so little to add to-day that I cannot help being struck by the fact that, despite various disguises, the intrinsic sources for the generation of ultra-violet light remain the same.

One technical point I should like to make is that the mercury vapour lamp is the only lamp that can be made to run easily, efficiently, and consistently on alternating current, which in the near future will be the current supplied to practically all districts. The mercury vapour lamp is therefore likely to find an increasing market, especially among medical practitioners, who will be content with one lamp.

Tests for Efficiency.

Various methods have been devised for the measurement of the actual quantity of ultra-violet light given to a patient, but one and all, I am glad to say, have had to be given up and dosage graded as a result of clinical experience. Dosage in ultra-violet light cannot be determined by mere rule of thumb; the response of individuals to this form of energy varies so widely that only by treating the individual, and not the average, can satisfactory results be obtained.

If, therefore, from clinical experience of the physical and pathological condition of a patient we decide that a dose just short of one that would produce an erythema is necessary, we can only ensure this by test doses *with* the lamp that is to be used; *on* small portions of the skin that is to be treated; and *at* the distance at which such treatment is to be carried out. This is the only method for measuring dosage that can safely be relied upon. If, in a busy department, other methods have to be employed, then initial dosage must be based on the assumption that each patient has a maximum degree of sensitivity, otherwise overdosage will inevitably occur.

Physical and Physiological Effects from Applications.

From the many theories of the physical effects of light and the consequent physiological response of the body, only one has emerged really clearly—namely, that cholesterol exists near the surface of the skin, and that irradiation of this manufactures vitamin D, which, when absorbed, improves the nutrition of the body. A number of workers are inclined to consider that this is the only effect of ultra-violet light on the body. But to limit the effects of ultra-violet light in this way is a mistake, for even a brief clinical experience with this method of treatment shows that the most striking feature of all is the variety of response shown by patients.

We know from the work of Colebrook, Hill, Eidinow, and others that, experimentally at any rate, temporary increase of the haemo-bactericidal properties of the blood can be secured. We also know that certain parts of the ultra-violet light spectrum are capable of inhibiting the growth, or even of killing certain kinds of bacteria. Careful observers have also suggested that these rays are capable of coagulating albumin, thereby destroying the superficial cells of the skin, with the result that a kind of protein shock may follow the absorption of these destroyed cells.

Professor Dixon has advanced the interesting theory that fluorescent substances in the skin, such as quiniodine, when irradiated, can become toxic to micro-organisms, and that this toxic substance can stimulate nerve endings. The best attitude to adopt to-day is, therefore, one of patient inquiry and close clinical observation, remembering, however, as Professor Dixon emphasized at Cardiff, that artificial ultra-violet light contains wave-lengths not found in natural sunlight, and is therefore essentially different.

Type Methods of Application.

In reviewing the very large number of cases that have now passed through the light department of the Royal Free Hospital it is seen that treatment by ultra-violet light is of four types. For want of a better terminology these may be called: (1) destructive, (2) counter-irritant, (3) stimulative, (4) sedative.

1. The destructive type of treatment is best exemplified by the Finsen-Reyn treatment of lupus and allied conditions. In lupus, unless the treatment is actually pushed until destruction of at least part of the irradiated tissue is secured, permanent improvement in the lupus nodules will not result. Similarly, destruction of lymphoid tissue in tonsils and throat can only be effectively achieved if the local dose is sufficiently strong to secure an intense inflammatory reaction, and it is obvious that a reaction of this nature is not to be preferred to clean surgery where this can be carried out.

2. In a counter-irritant dose a definite degree of erythema should be secured, and is indicated in exactly the class of case in which the old-fashioned mustard plaster would have been used. This type of effect can be secured locally—that is, over a single chronic joint—by means of the Kromayer lamp, which, applied directly to the skin, is capable of achieving an intense erythema in sixty seconds or less. Another method of producing the same effect, but over a wider area, is by exposing the body in areas of about eight inches square at a time, and producing a bright erythema after initial test measurement. This method is the method of Dr. Eidinow, and, according to his researches, produces the best haemo-bactericidal response.

3. Stimulative effects are apparently best produced by doses of ultra-violet light that do not produce an erythema, and may consequently be called sub-erythema doses. These may be given to large areas of the body. This method of treatment is one that would obviously be chosen, therefore, in conditions such as rickets and other diseases of malnutrition, and the carbon arc is the apparatus of choice.

4. Sedative effects are secured when the dose is about 25 per cent. of an erythema dose and the area of the skin exposed at each treatment is not more than about 10 per cent. of the body. Phthisical patients without pyrexia, cases of burns, and patients in physically debilitated states respond best to this method of treatment.

These methods have been set out very briefly, and exact details have purposely been avoided. Age, physical condition, race, disease, type of lamp employed, and many other variables have all to be taken into consideration. Nor has any attempt been made to bring out the effects of ultra-violet light on the body when its temperature is altered either by heating or cooling the skin before, during, or after treatment.

Conditions for which Ultra-violet Light is the Treatment of Choice, and Some Others that call for Special Remarks.

Having briefly reviewed the nature of ultra-violet light apparatus, tests for efficiency, and possible physiological effects, one comes naturally to a consideration of the conditions that are helped by this method of treatment. It is, however, just this aspect of the subject that presents the greatest difficulty. A study of the literature reveals the fact that nearly every disease has been claimed by one or another author to have been cured, or at any rate greatly relieved, by exposures to ultra-violet light. Such wide claims naturally bring the method into discredit, and are entirely unjustified and misleading.

Statistics of cures are extremely likely to lead to error unless most carefully handled, and unless they cover long periods of time and a very large number of cases. I have therefore prepared an alphabetical list of every ailment mentioned as having been treated by ultra-violet light in a number of books on the subject. I have "combed out" this list several times, rejecting many conditions, either because the evidence of the value of ultra-violet light was bad, or because my own personal experience convinced me that such treatment was a waste of time. In the final list I endeavoured to leave all those conditions in which (*a*) I have had, or seen, gratifying results; in which (*b*) I considered light should be tried with a reasonable prospect of benefit in a percentage of cases, and (*c*) about which I wished to sound a particular warning note.

Since the war the majority of medical practitioners have become familiar with the system of assessing disability as a percentage; and in my list I have noted against each disease my own estimation of the value of light treatment for that disease, 100 per cent. meaning that ultra-violet light is not only the treatment of choice but will yield a high percentage of cures, 50 per cent., that light is well worth trying and that a considerable number will benefit from its use, and so on down to zero. Even with this guide I have found it necessary to add some explanatory remarks.

The list probably contains diseases that might well have been "combed out," and omits others that could have been incorporated with advantage. Also I am fully aware that my attempted valuation is merely an abbreviated method of stating my own opinion and will not find universal agreement, but in the preparation of this list I have endeavoured to provide a general guide which errs on the side of caution.

LIST OF AILMENTS TREATED BY ULTRA-VIOLET LIGHT.

In the following list the type of treatment recommended appears immediately after the ailment, the author's assessment of the value of light treatment is shown in parentheses, and his remarks follow in separate paragraphs.

Alopecia. Counter-irritant. (50 per cent.)
Without an erythema lasting results appear never to be obtained and the scalp requires large doses. Treatment every five days is ample.

Asthma. Sedative. (15 per cent.)
Stimulative or counter-irritant doses help a few cases, but more frequently do harm.

Boils. Counter-irritant or even destructive. (10 per cent.)
The Kromayer lamp utilizing the quartz rods is best.

Bursitis. Counter-irritant. (75 per cent.)
Intense erythema is essential, and the Kromayer lamp should be used.

Burns. Sedative. (90 per cent.)
Two minutes of the mercury vapour lamp at 36 in. through a film of liquid paraffin is the best dose.

Catarrh. Stimulative. (40 per cent.)
One relies on the temporarily raised haemo-bactericidal properties of the blood to bring about a reaction to the infection.

Cervicitis. Counter-irritant. (20 per cent.)
Unless applied locally by means of Kromayer lamp and rods ultra-violet light seems to be of little benefit in this condition.

Conjunctivitis. Sedative. (20 per cent.)
Requires very special technique, and is not safe without practical instruction.

Corneal ulcers. Sedative. (20 per cent.)
Requires very special technique, and is not safe without practical instruction.

Debility. Sedative at first, stimulative later. (80 per cent.)
Probably the most responsive of all general ailments to ultra-violet light, provided erythema doses are avoided and there is no "master" ailment inhibiting benefit.

Dermatitis. Sedative. (5 per cent.)
Many of these cases unless carefully selected are made worse by ultra-violet light.

Fractures (delayed union of). Counter-irritant. (70 per cent.)
A very valuable adjunct in securing union; should be used in conjunction with cathodal galvanism.

Furunculosis. Stimulative. (75 per cent.)
The mercury vapour lamp yields the best results in these cases.

Glands (Tuberculous). Sedative. (80 per cent.)
Tuberculous glands react well in a high percentage of cases provided small initial doses are given.

Impetigo. Stimulative. (65 per cent.)
Results if observed over long periods are usually unsatisfactory, however good the initial response.

Lumbago. Counter-irritant. (30 per cent.)
A small percentage yields brilliant results provided the lumbago is not secondary to some other disease.

Lupus. Destructive. (95 per cent.)
Should only be treated where a Finsen-Reyn lamp treatment can be obtained under a skilled operator.

Marasmus. Sedative. (60 per cent.)
These children almost always require concomitant abdominal diathermy if benefit is to be rapid, genuine, and maintained.

Neuralgia. Neuritis.
Frequently exacerbated by ultra-violet light, and almost always by erythema doses.

Osteo-arthritis. Stimulative or counter-irritant. (35 per cent.)
Light should always be given a trial, particularly in patients of Jewish extraction, but many disappointments and failures occur.

Phthisis. Sedative. (35 per cent.)
Of all conditions the one that calls for the greatest care and watchfulness on the part of the physician, and records of weight, temperature, etc., should be kept.

Pruritus.
Results, despite fantastic claims to the contrary, are most disappointing.

Psoriasis. Stimulative. (15 per cent.)
Results, if observed over long periods, are usually unsatisfactory, however good the initial response.

Rickets. (*a*) Sedative, (*b*) Stimulative. (80 per cent.)
The efficient formation of vitamin D can best be started by small doses, especially in cases with extensive changes.

Synovitis.
No general guide can be laid down, as the nature and present condition of the synovitis are of prime importance in selecting treatment.

Ulcers. (*a*) Sedative, (*b*) Stimulative. (30 per cent.)
Moderately small doses should be tried first; if no response, chronic ulcers are well worth treating with counter-irritant doses.

The foregoing list, which even after many "comb-outs" still contains twenty-seven conditions, includes only seven in which I have estimated ultra-violet to have a value of 75 per cent. or over. That the valuation is approximately correct I have little doubt, just as I have complete faith that ultra-violet light treatment constitutes a valuable advance in modern therapy if a sober view is taken of its field of activity.

Conclusion.

Before drawing this review to an end I would like to refer briefly to a small investigation that has just been completed, thanks to the facilities given me by Professor Mellroy, and to the unsparing work of Dr. Bunbury, my late clinical assistant. In this investigation the mothers of every alternate baby born in the maternity wards at the Royal Free Hospital from January to June were given a series of doses of light, and record was kept of the weights of their babies at birth, at 11 days, at 6 weeks, and at 12 weeks. The remaining babies constituted the controls. In this way approximately 1 ton weight of babies have been observed. Though the final figures have not yet been collated it is possible to state that the increase of weight of sixty-five babies whose mothers had had irradiation was *plus* 28.5 per cent. at the end of six weeks, and of a similar non-irradiated group *plus* 29.3 per cent. All other figures are on the same scale, and indicate how careful one must be before claiming that "light treatment" is "wonderful" for nursing mothers or for any other purpose.

In the near future, however, I hope to see such genuine knowledge of this subject that prescriptions with full instructions as to lamp, distance, dose, area of skin exposed, etc., will be the rule rather than the rare exception. I hope also that when these prescriptions are not dispensed by the doctor they will be given in writing, as an ordinary prescription is given to a chemist, to workers on a national roll compiled as recommended in Cardiff by the Representative Body.

ABDOMINAL ANEURYSM CAUSING THROMBOSIS OF THE INFERIOR VENA CAVA.

BY

KENNETH P. FOOKS, M.B., CH.B.,

BIRMINGHAM.

THE following case is worthy of being recorded by virtue of the rarity of the condition, the very unusual course of the disease, and the difficulty experienced in reaching an accurate diagnosis until a catastrophe preceding a fatal termination made it obvious.
